| Public reporting burden for the collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204, Arlington VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to a penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number. |                                    |                                     |                                          |                                          |                                 |

# What is the Problem?

Time-sensitive systems in uncertain environments have complex behaviors. How do we validate correct timing in such systems?

- Exact probabilistic verification is infeasible due to model size
- Black box testing does not yield bounded predictions
- Need formal approach for dealing with uncertainty
  - Accurate, bounded, probabilistic results
  - In reasonable time even for rare outcomes

Use statistical model checking to do a “smart sampling of the world”

- Simulation captures both random variables and timing (scheduling)
- Importance sampling “tilts” input distributions for efficient probability estimation of “rare” events

Note: We use “probability estimation” based statistical model checking. There is also a “hypothesis testing” based version.

# Statistical Model Checking (SMC)

- System properties described in formal language (UTSL, BLTL, etc.)
- Property is tested on “sample trajectories” (sequence of states)
- Each outcome can be treated as a Bernoulli random variable (i.e., coin flip)

# Probability Estimation with SMC

## SMC Basics

- Indicator function  $I(\vec{x}) = 1$  iff property holds for input  $\vec{x}$ .
- Relative Error  $RE(\hat{p}) = \frac{\sqrt{\text{var}(\hat{p})}}{E[\hat{p}]}$  is measure of accuracy.
- Draw random samples from input distribution  $f(\vec{x})$  until target Relative Error is met.
- Estimated probability that property holds is:

$$\hat{p} = \frac{1}{N} \sum_{i=1}^N I(\vec{x}_i) = \frac{1}{10} = 0.1 \quad RE(\hat{p}) = \frac{0.32}{0.1} = 3.2$$

## Importance Sampling

- Modify input distribution to make rare properties more visible.
- Weighting function  $W(\vec{x})$  maps solution back to original problem.
- Reduced relative error with same number of samples.

$$\hat{p} = \frac{1}{N} \sum_{i=1}^N I(\vec{x}_i) W(\vec{x}_i) = \frac{0.2 + 0.5 + 0.3}{10} = 0.1$$

$$RE(\hat{p}) = \frac{0.18}{0.1} = 1.8$$

# Osmosis SMC Tool

Osmosis is a tool for Statistical Model Checking (SMC) with Semantic Importance Sampling.

- Input model is written in subset of C.
- ASSERT() statements in model indicate conditions that must hold.
- Input probability distributions defined by the user.
- Osmosis returns the probability that at least one of the ASSERT() statements **does not** hold.
- Uses dReal<sup>1</sup> solver to build  $I^*(\vec{x})$ .
- Simulation halt condition based on:
  - Target relative error, or
  - Set number of simulations

<sup>1</sup> <http://dreal.cs.cmu.edu/>

## Osmosis Main Algorithm

1. Generate approximation of fault region

2. Conduct SMC and calc. failure prob.

a)  $\hat{p}_{raw} = \frac{5}{20}$  ← # in Fault / ← Total #

b)  $p^* = \frac{6}{64}$  Fraction of input  $I^*(\vec{x})$  covers

c) Failure prob. estimate is product of two values

$$\hat{p} = \hat{p}_{raw} p^* = 0.23$$

# $I^*(\vec{x})$ Generation Algorithm

Fault  
Region

Algorithm:

1. Set the current “cube” as the full range of all inputs.
2. Apply dReal to the current cube.
3. If the result is “SAT”, split cube into two equal probability cubes on one variable, and recursively apply at Step 2.

# Example: Air Hockey Problem

## Air Hockey Problem

- Table with a moving puck and a fixed target.
- Puck rebounds without friction.

## Inputs

- Angle – Initial angle at which puck is hit.
- Distance – Total distance of travel for puck.

## Failure Condition

- Puck stops on target (red dot).

## Challenges

- Multiple failure areas in input space.
- Complex structure of failure area.

# Fault Map for Air Hockey Problem

Fault map shows area of input space where faults are located.

- Plotted in CDF space.
- **Green** area indicates input space included in  $I^*(x)$ .
- **Red** area indicates input space include in  $I(x)$ .

# Sample Size vs Recursion Depth (Air Hockey)

Simulation effort with SIS decreases exponentially with recursion depth.

# $p^*$ vs Recursion Depth (Air Hockey)

Upper-bound  $p^*$  becomes more accurate as recursion depth increases.

# Effect of SIS Optimizations

## Optimization 1

No call to dReal if first child call is unsat.

## Optimization 2

Use counter-example from parent to avoid dReal calls on children.

Optimization 2 results in greatest benefit with factor of two reduction in number of calls to dReal. Small additional benefit by combining both methods.

# Conclusion

## Semantic Importance Sampling

- Create approximation of fault region using abstraction.
- Create an alternate input distribution for importance sampling.
- Level of approximation (recursion depth) is user tunable.
- Can reduce SMC sample size by orders of magnitude.

## Osmosis tool

- Applies semantic importance sampling on a C-like specification.
- Uses the dReal SMT solver to build approximate fault region model.
- Can be applied when there are multiple fault regions.
- Optimization techniques can nearly halve number of dReal tests required.
