Report Title

Final Report: Preparation of Phase-Locked Molecular Quantum States

ABSTRACT

To coherently control molecular collisions using a superposition of molecular quantum states, part of the DURIP equipment money was utilized to fabricate a high vacuum molecular beam reaction chamber. To obtain high resolution angular distributions, the reaction chamber has been designed with a velocity map imaging facility. The velocity map imaging comprises a couple of ion lenses, a flight tube and a high-resolution position sensitive RoentDek delay line detector. Another part of the DURIP equipment money was also utilized to acquire an injection-locked Q-switched Nd³⁺:YAG laser which provides both the nanosecond single-mode pump for the Stark induced adiabatic Raman passage (SARP) as well as the pump for the single-mode pulsed dye laser amplifier. Using this equipment we are now ready to demonstrate for the first time quantum interference in a single molecular collision.

Preparation of Phase-Locked Molecular Quantum States

To understand a collision process ($D+H_2 \rightarrow HD+H$) at the quantum level our goal is to experimentally study the scattering dynamics by preparing the target molecule (H_2) in an addressable single or a coherent superposition of quantum states. To prepare a target molecule in a desired rovibrational M-quantum state within the ground electronic surface we introduced a new coherent optical technique called Stark induced adiabatic Raman passage (SARP). We have demonstrated SARP successfully transferring nearly the complete population of the ground $H_2(v=0, J=0)$ molecule to a vibrationally excited $H_2(v=1, J=0, 2, M)$ state, thus reaching the first milestone of the proposed project. More recently, SARP has achieved the second important milestone by preparing a target H_2 molecule in a coherent superposition of M-states within a single rovibrational ($v=1, J=2$) energy eigenstate thus, preparing where, the complex coefficients of superposition are controlled by mixing various polarizations of the pump and Stokes laser pulses.

To reach our final goal to control scattering processes using the coherent superposition of quantum states, part of the DURIP equipment money was utilized to fabricate a high vacuum molecular beam reaction chamber. This reaction chamber provides a highly collimated molecular beam, which is essential for preparing the collision partners in addressable quantum states with well-defined relative velocity. To obtain a high-resolution angular distribution (differential cross-section) we fabricated the reaction chamber that allows velocity map imaging of the scattered molecules, which are detected state selectively using resonance enhanced multiphoton ionization. The velocity map imaging has been made possible by designing a mass-spectrometer, which consists of ion lenses, a flight tube and a high-resolution position sensitive RoentDek delay line detector. A part of the DURIP equipment money was also utilized to acquire an injection-locked Q-switched Nd^{3+} :YAG laser which provides both the nanosecond single-mode pump for the SARP excitation as well as the pump for the single-mode pulsed dye laser amplifier. Using the reaction chamber and the single-mode nanosecond tunable laser pulses we are now equipped to demonstrate for the first time quantum interference in molecular scattering, which is analogous to the Young's double slit experiment.

Our immediate goal is as follows:

1. Study inelastic three- and four-atom scattering dynamics using a SARP prepared target molecule in a single rovibrational M-state and compare experiment with theory.
2. Utilize SARP with appropriate pump and Stokes laser pulses to reach higher vibrational excited states of H_2 . By stretching the bond length our purpose is to explore regions of the reaction potential with possible curve crossings (conical intersection).
3. Demonstrate M-state interference in dynamical stereochemistry and retrieve the phase information of scattering amplitude.
