Report Title

Final Report: Multi-angle Light Scattering Device for Aerosol Particle Detection

ABSTRACT

The goal of this work was to build a device to study light scattering by irregularly shaped particles and analyze that scattering from a unique perspective so that light scattering can be used to detect pathogenic and explosive aerosol materials, and discriminate between them and naturally occurring ambient particles in a real-time, field-implemented instrument. Such an instrument is a primary defense need. The major road block to the use of light scattering for nefarious aerosol detection and discrimination lies in the fact that the particles involved are usually irregularly shaped, and light scattering from such particles is not well understood. This proposal addressed this deficiency by constructing a multi-angle light scattering device to measure the scattering matrix of irregularly shaped particles. Unique features of the device are simultaneous multi-angle detection and detection from extreme forward (0.3 deg) to backward scattering angles (160 deg). We are currently measuring scattering from Arizona road dust, various sizes of abrasive grits and planning soot studies, some cloud processed. The project has applied our unique Q-space analysis method to find power functionalities. The device is at the center of a comprehensive program to study light scattering that will involve and train graduate, undergraduate and high school students.

Scientific Progress

Our most significant progress to date (Dec 1, 2014) is the construction of the multi-angle light scattering detection device. This device allows for simultaneous measurement of scattering for 31 angles ranging from 0.3 to 160 degrees. This device measures all the relevant components of the scattering matrix. We have also built a device for backscattering for angles ranging from 170 to 180 degrees. This device measures scattering for both linear polarizations. We separated these two devices because the backscattering gives us special problems that need to be worked out before we combine the two devices for simultaneous detection at 0.3 to 180 degrees.

We have begun studies of scattering from three different sizes of Arizona road dusts and five different grit sizes of alumina abrasives. With our small angles (and unlike all previous scattering work), we are able to obtain Guinier regimes for these systems despite their large sizes (as large as 15 micron). Hence an optical measurement of size is obtained. At larger angles, hence larger q values, where q is the scattering wave vector, power laws have been found. This result is new and in corroboration with our previous work involving spheres, reanalysis of dust scattering data and perturbed sphere theory predictions. Thus our hypothesis that Q -space analysis will yield power laws with quantitative exponents is unfolding to be true. Future work involves rebuilding the apparatus to close a gap in the scattering angles near 15 degrees, obtain and use more sensitive detectors, and then a comprehensive study of scattering for a wide range of particle shapes, sizes and compositions.
