

Report Documentation Page				Form Approved OMB No. 0704-0188	
Public reporting burden for the collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204, Arlington VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to a penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.

LONG-TERM GOALS

This project aims to involve one graduate student into intensive study of dynamics of cracks in sea ice. The parent ONR grant does not include a student support.

OBJECTIVES

In this project we measured crack velocity as a function of ice microstructure, temperature and a load applied to ice. Experimental techniques based on electromagnetic measurements are used to determine crack velocities in various types of ice. Special attention was given to the dynamic interaction between cracks growing in ice and such micro structural ice features as brine pockets, brine channels and grain boundaries. Such interactions plus the high ductility of sea ice are suspected to be responsible for the very low velocity of cracks in sea ice. Results were analyzed according to recent advances in the general theory of crack dynamics and crack interaction. It is expected that this work will answer the question of why sea ice cracks have such low velocity and contribute to the understanding of the dynamics of ice fragmentation.

APPROACH

Experimental techniques based on measurements of electromagnetic emissions (EME's) from cracks and changes in ice electrical conductance and capacitance were used to determine crack velocities in various types of natural and artificial ice. The techniques are characterized by high-time resolution ($< 1\text{ms}$) and the capability to detect micro cracks (1 mm^2).

SCIENTIFIC/ TECHNICAL RESULTS

None. The student was hired two weeks ago.

IMPACT FOR SCIENCE

We expect to establish the micro-mechanically based modeling of dynamic fracture of sea ice. The maximal crack speeds in ice (that set limits to the rates of fragmentation and of ice-breaking operations) will be predicted as functions of the microstructure (density and shapes of fluid inclusion, geometry of microchannel network) and of the physical properties of the fluid (density, viscosity and surface tension).

We will also predict the forces arising during the fragmentation of ice, thus making it possible to roughly estimate the maximal forces in ice-structure interactions for a given speed of ice sheets advance.

The expected results will also be relevant for other materials that contain fluid inclusions.

TRANSITIONS

None
