TABLE OF INTERPLANAR SPACINGS FOR CRYSTAL-STRUCTURE DETERMINATIONS

BY X-RAY DIFFRACTION WITH MOLYBDENUM, COPPER,

COBALT, IRON, AND CHROMIUM RADIATIONS

By J. Howard Kittel

INTRODUCTION

A widely used technique in X-ray-diffraction investigations consists in placing a powdered or small polycrystalline specimen in a Debye-Scherrer camera and allowing a beam of monochromatic X-rays to fall upon the specimen. A fraction of this primary beam of X-rays will be diffracted by the specimen. The diffracted rays leave the specimen in the form of cones, the axes of which are identical with the primary X-ray beam. The cones of diffracted X-rays, if allowed to fall on a sensitized film in a Debye-Scherrer camera, will produce a pattern of arcs which are symmetrical about the axis of the undeviated primary X-ray beam. If the dimensions of the camera and the wave length of the X-rays are known, it is possible to compute the spacings of the atomic planes of the crystalline specimen from the distances of the arcs from the primary beam. A knowledge of the interplanar distances d will provide information, often not obtainable by other methods, regarding the crystal structure and chemical composition of the specimen, the identification of phases present, and the determination of grain size, solid solubilities, and the presence of internal and applied stresses.

For a simple diffraction pattern, the time required to calculate interplanar distances from measurements of the pattern is not excessive. If more than a few lines are present, however, or if several simple patterns are to be studied, it is very advantageous to have available a table giving interplanar spacings directly in terms of the linear measurements made on the film of the lines appearing in the diffraction pattern. The preparation of a table was undertaken at the NACA Cleveland laboratory when the expansion of research involving X-ray diffraction techniques indicated that such a table would greatly decrease the time

required to analyze diffraction patterns. The table was prepared for use with $K\alpha_1$ radiation from the following target materials: molybdenum, copper, cobalt, iron, and chromium. The d values for cobalt were obtained from reference 1. The sine values of the angle θ formed by incidence of the primary X-ray beam on an atomic plane were obtained from reference 2 and range from 0 to 1.0000. The d values for molybdenum, copper, iron, and chromium were calculated by the Computing Section of the Engine Research Division under the direction of Miss Margaret L. Strickland.

DESCRIPTION OF TABLE

Symbols and Units

- R distance in millimeters, measured on film, between central point and arc of a diffracted line on a pattern made in a camera 143.2 millimeters in diameter
- R' distance in millimeters, measured on film, between central point and arc of a diffracted line on a pattern made in a camera having a diameter other than 143.2 millimeters
- θ angle in degrees formed by incidence of primary X-ray beam on an atomic plane
- $K\alpha_1$ most intense part of characteristic X-ray spectrum of each radiation listed in table
- λ wave length in angstrom units of X-rays being scattered
- d interplanar distance in angstrom units in a particular set of atomic planes in a crystal

Equations Used in Calculations

For the type of powder diffraction pattern made in a Debye-Scherrer camera, the central spot is most easily found by locating the midpoint of the distance $2R$, measured on the film, between arcs formed by the same cone of diffracted X-rays. When the central point is located, the R values for the remaining diffraction lines can be readily measured.

The table was computed for direct use with a commercially obtainable Debye-Scherrer camera 143.2 millimeters in diameter

now being used at this laboratory. For a camera of this diameter the following relation gives θ in terms of R :

$$\theta = 0.4R$$

The angle θ was calculated for values of R ranging from 0.1 millimeter to 225.0 millimeters in increments of 0.1 millimeter. In order to compute the interplanar spacing d for each value of R , the sine of the corresponding value of θ was inserted in the Bragg equation

$$\lambda = 2d \sin \theta$$

The values of $\sin \theta$ ranged from 0 to 1.0000.

The wave length λ was determined by the target material of the particular X-ray tube being used. Tubes with targets of molybdenum, copper, cobalt, iron, and chromium are now in use at this laboratory. Values of R against d are listed in the table for $K\alpha_1$ radiation from each of these target materials. The values of wave length for each $K\alpha_1$ listed were obtained from reference 3 and are as follows:

Mo $K\alpha_1$	0.7078
Cu $K\alpha_1$	1.5374
Co $K\alpha_1$	1.7853
Fe $K\alpha_1$	1.9321
Cr $K\alpha_1$	2.2850

Although the d values were calculated for as many as five significant figures, ordinary work will require the use of only three or four figures. For precise work all five figures can be used.

APPLICATION OF TABLE

For use with a Debye-Scherrer powder camera having a diameter of 143.2 millimeters, the table may be used directly by first locating a value of R measured from a diffraction pattern and then reading the corresponding d value listed for the particular radiation used.

For example, if R is found to be 56.1 millimeters and if Cu $K\alpha_1$ radiation was used, the d value of the particular diffraction line measured is 2.0138.

The table may also be applied to measurements of patterns made in cameras of diameters other than 143.2 millimeters by first multiplying the measured R' value by the ratio of the two camera diameters and then locating in the table the new value of R thus obtained.

For example, if a 57.3-millimeter-diameter camera is being used and if a value of R' from a pattern made with this camera is found to equal 35.7 millimeters, then R is found as follows:

$$R = R' \times \frac{143.2}{57.3} = 89.2$$

The value of R thus obtained is located in the table and the corresponding d value is found as before.

It is also possible to apply the table to measurements of patterns made in cameras other than the Debye-Scherrer type by using the value of $\sin \theta$ for each diffraction line instead of R to locate corresponding d values.

For example, if a transmission pattern made of a thin polycrystalline specimen is recorded on a flat film, a pattern consisting of a number of concentric Debye rings will be obtained. If $\text{Mo K}\alpha_1$ radiation was used, and if the diameter of one of the rings is found to be 68.0 millimeters and the film specimen distance is 50.0 millimeters, then

$$2\theta = \tan^{-1} \frac{34.0}{50.0} = 34.22^\circ$$

From the values of $\sin \theta$ in the table the value of d is found to be 1.203.

ABSTRACT

This table was constructed to permit a time saving in the analysis of complex diffraction patterns obtained with a Debye-Scherrer camera on powdered or small polycrystalline specimen. The table shows the interplanar spacing in Angstrom units of molybdenum, copper, cobalt, iron, and chromium obtained with $K\alpha_1$ radiation for angles of incidence, whose sines range from 0 to 1.0000.
