PREFACE

In the present survey of the Antiradiation Drug Development Program of the U.S. Army Medical Research and Development Command, an attempt has been made to assemble in one place all of the compounds that were synthesized along with the associated mouse test results and offer an interpretation of the biological data *vis a vis* the structures of the compounds. This edited body of data has been organized for quick and easy reference both for those working in the field and for the casual reader. It was not the intention to report on all of the work that was done in the Program. The arbitrary decision was made not to extend the survey to include results of indepth studies that were carried out on a number of the more interesting compounds; such studies could include, for example, determination of a dose reduction factor, duration of action and mechanism of the chemical antagonism of anti-radiation action. Results on the testing of selected compounds in large animals have also been omitted. Finally, results of the various preclinical pharmacology studies that were carried out to support the requests for exemptions to conduct clinical studies of drug tolerance, as well as the results of the tolerance studies, have also been omitted.

There are two principal parts of this survey. One, which may be considered the survey proper, is a large table simply entitled Survey. In it is summarized the results of the testing of all of the target compounds synthesized in the program as well as a small number of related gift compounds that seemed to be of sufficient interest to include. The other principal part, following the survey proper, is a discussion of structure-activity relationships among selected series of compounds along with 47 tables of associated data. The latter tables contain only a small portion of the compounds that are included in the Survey.

Many people contributed to the success of the program over its active years, not only those associated with it at the Walter Reed Army Institute of Research, but also those at the Headquarters, U.S. Army Medical Research and Development Command as well as those associated with the many contractors. Special mention must be made of Dr. David P. Jacobus whose initiative and inspiration provided the impetus for the program and who served as its technical director during its most active years. Succeeding Dr. Jacobus was Dr. William E. Rothe who directed the technical program until its termination in 1973.

The author is indebted to June A. Page, Larry J. Hooks, Sandra M. Simpson and Ruby N. Boyd for technical assistance in the collection of data for this survey and to Marie M. Grenan for assistance in the collection of biological data and consultation on their interpretation. Special thanks and acknowledgement is made to David P. Jacobus for consultation and suggestions for valuable inclusions in the survey.

LIST OF TABLES

Table No.	Page
1. 3-(2-Mercaptoethylamino)propioamide and Derivatives. Effect of Varying the Thiol-blocking Group.	691
2. 2-(3-Aminopropylamino)ethanethiol and Derivatives. Effect of Varying the Thiol-blocking Group.	692
3. n-Decylaminoethanethiol and Derivatives. Effect of Varying the Thiol-blocking Group.	693
4. 2-Aminoalkylthiols.	694
5. 2-Aminoalkylthiosulfuric Acids.	695
6. 2-Aminoalkylphosphorothioates.	696
7. 2-Mercaptoalkylamines.	697

INTRODUCTION

In the spring of 1959 the U.S. Army Medical Research and Development Command initiated a program of drug development for chemoprophylactic agents that could protect troops against ionizing radiation. The technical part of the program was the responsibility of the Walter Reed Army Institute of Research and was initiated under the technical direction of Dr. David P. Jacobus. The quantitative biological data that were generated in the program were originally classified but the program was declassified in 1965.

Although there was a parallel in-house effort, the bulk of the chemical synthesis was carried out through research contracts with industry, research institutes and universities. Most of the biological testing and pharmacology was done in-house although it eventually became necessary to supplement the in-house efforts with appropriate contracts. The large number of chemicals and the large volume of chemical and biological data necessitated the development of computerized methods of handling (1,2,3,4).

The program was planned and organized in such a way that all of the elements necessary for modern drug development were phased in at appropriate times. Thus while rational synthesis and primary testing were emphasized at the outset of the program, there followed in timely succession the program elements of advanced screening in large animals, indepth studies on compounds of interest, preclinical pharmacological studies, formulation investigations, preparation and appropriate review of the necessary documentation for human tolerance studies, and, finally, human tolerance studies. A total of about 4400 target compounds were synthesized in the program. Five formal requests for new drug exemptions (INDs) were prepared and human tolerance studies were conducted on three of these.

Prior to the advent of the Army program there had accrued a considerable body of data that indicated the feasibility and desirability of such a study. The Atomic Energy Commission had evaluated the mechanism of action of ionizing radiation, characterized the syndromes associated with radiation mortality and sponsored studies on the mechanism of action of thiol derivatives in various rodents, microorganisms and *in vitro* cultures. Patt in 1949 (5) had shown that cysteine, administered before irradiation with x-rays, brought about a substantial reduction of radiation injury in rats. Two years later it was demonstrated that the cysteine analog, cysteamine (MEA), protected mice if administered before x-irradiation (6). Both of these compounds contain unsubstituted amino and thiol groups. In 1955 it was reported that S-2-amino-ethylisothiuronium bromide hydrobromide (AET) had good antiradiation activity (7) and, finally, in 1959 the good radioprotective properties of

2-aminoethylthiosulfuric (the Bunte salt of MEA) were reported (8). Also, by the time the program began, about 1500 compounds had been tested elsewhere, mainly at the U.S. Air Force Radiation Laboratory in Chicago (9). The best compounds from this group were those having a potential thiol group separated by 2 or 3 carbons from a basic nitrogen function.

In this same pre-program period, Eldjarn and Pihl (10) had provided a possible theoretical basis for the mechanism of action of the thiol compounds against radiation-induced radicals (indirect action) and against the radiation itself. They suggested that mixed disulfide formation of the protective thiol with essential thiols of the target molecule shields the latter by providing a non-lethal target for radiation-induced radicals and a source of electrons (the disulfide bond) for repair of an electron deficiency elsewhere in the molecule, both processes leading to a regeneration of the original essential thiol.

Many studies had been conducted on methods of modifying the response to sub-lethal radiation as opposed to fully lethal radiation. Survival against sub-lethal radiation could be improved by modification of host defense. Thus, non-physiological materials can stimulate the reticuloendothelial system to produce leucocytes or enhance the defense against bacterial invasion (antibiotics) and can offer very significant protection against mid-lethal radiation. Partial shielding will also offer protection. In general, where appropriate experiments have been conducted, such manipulations work in concert with the aminothiols, *i.e.*, reduction of lethal radiation to mid-lethal by administration of an aminothiol would provide an animal that could be effectively treated with antibiotics. On the other hand, these host procedures were relatively ineffective in animals exposed to fully lethal radiation. Because the objective of the program was to develop antiradiation drugs rather than modifying host defense, almost all of the radiation experiments and test procedures were conducted at fully lethal radiation. As pointed out in the description of the biological methods, none of the 44,000 mice used as controls for the approximately 4400 compounds tested survived and none showed early deaths.

The pivotal decision to initiate the Army Program was made after Jacobus and Dacquisto (9) found that an intravenous administration of a mixture of compounds containing at least two mercaptans, a methemoglobin-producing agent and a cytochrome inhibitor could protect dogs exposed to approximately twice a lethal dose of radiation. The protected dogs received no post-exposure care and maintained white counts sufficient to offer protection against disease. These experiments raised the possibility that such protective activity could be extended to higher animals.

The studies initiated by Patt and continued by others demonstrated that the aminothiols had the ability to reduce irradiation injury by a factor of approximately 2. That is to

say, the apparent dose of radiation would appear to be half of what the animal actually received. By a judicious selection of the dose, it was then possible to demonstrate that an animal receiving sufficient radiation to cause the CNS death syndrome would have the apparent dose of radiation cut in half so that the fatal syndrome would then be the GI syndrome. Likewise, the GI syndrome could be reduced to the bone marrow syndrome and the bone marrow syndrome could be converted to survival. These dose reductions in mice were subsequently repeated in the Army program using both monkeys and dogs. In the Army program, therefore, it was considered that any compound effective against lethal radiation would offer a comparable dose reduction factor for a super-lethal radiation. Dose reduction factors as conventionally determined in radiobiology were very rarely studied in the Army program. However, the reader may obtain an approximation of the magnitude of the dose reduction by noticing that any compound that received an antiradiation rating of "+", indicating at least 50% survival at the dose tested reduces the apparent dose of radiation from the LD₁₀₀ of 800r to at least the LD₅₀ of 600r. Therefore at the dose tested the compound would have a dose reduction factor (DRF) of at least 1.3 (800/600). Many of the compounds tested allowed 100% survival at 800r. Since the LD₁₀ of radiation for mice in the absence of drug was approximately 450r the DRF for compounds allowing 100% survival was at least 1.8 (800/450). These relationships can be appreciated from an examination of the following data showing actual dose reduction factors determined for WR-2721 [H₂N(CH₂)₃NHCH₂CH₂SPO₃H₂] and percent survival of WR-2721-treated mice subjected to otherwise lethal radiation. The compound was administered 15 minutes pre-irradiation, IP, for both sets of data.

Mortality Data on WR-2721-Treated Mice			
Dose (mg/kg)	Jackson Lab Data ¹	Survey Data	
	(DRF)	%Survival	Rating ³
75	n.d. ²	80	+
150	1.81	100	+,+
200	2.18	n.d.	
250	2.27	n.d.	
300	n.d.	100	+,+,+
350	2.42	n.d.	
500	2.71	n.d.	
600	n.d.	100	+,+,+,+

¹The Jackson Laboratory, Final Report 1 August 1968 - 31 July 1969, Contract No. DA-49-193-MD-2289.

²n.d. = not determined.

³The rating is that used in the Survey proper and explained in the introduction to the Survey. Only a rating of "+,+,+,+" for a dose of 600 mg/kg, which would include the lower doses, would appear in the Survey and would indicate that a dose level of 1/8th of 600 mg/kg gave at least 50% survival.

The background described established the setting for the program. Aminoalkylthiols, actual or potential, were considered to be the only compounds offering "true" radioprotection and even for these, there existed the possibility that their mechanism of action could be through production of anoxia. It was not the objective of the program to obtain compounds of this class with DRFs greater than 2-3 since it was felt that they had only one mechanism of action and might have a DRF limit of 2-3. Rather it was to obtain a compound that was capable of conferring significant protection at doses considerably below the highest tolerated level such as was required by the original aminoalkylthiols. In other words, a compound with a larger factor of safety (therapeutic index) was desired. From the practical standpoint, a small effective dose, comparable in weight with those employed in conventional therapy, and having a low incidence of side effects was desired. Finally, the ideal drug should be effective by oral administration.

Toward these ends the primary test was designed to measure two parameters precisely, viz., the effectiveness of a compound at the highest tolerated dose (semiquantitative DRF) and the ability of the compound to confer protection when administered at less than this dose. Normally, only one test of a compound was made if the compound exhibited no activity in a valid experiment as determined by the response of the control animals. When a compound exhibited interesting activity, the activity was confirmed, the compound was retested at lower doses and, in addition, usually tested by oral administration. The very best compounds were ultimately tested in dogs and/or monkeys although formal dose reduction studies were not conducted.

As mentioned earlier, the main thrust of the rational synthesis effort in the program was directed toward aminoalkylthiols and derivatives. Adherence to the thiol-blocking concept, discussed elsewhere in this survey, dictated the synthesis of compounds with several thiol-blocking groups for each parent compound synthesized. In retrospect, this was a sound approach but it required a substantial portion of the total synthesis effort and to some extent limited the number and variety of amine-function derivatives that could be synthesized. By exploring a large variety of thiol-blocking groups, the synthesis program can be credited with firmly establishing the worth and utility of a select few and, in addition, obtaining a good appraisal of the worth of a variety of classes of moieties attached to the amino function. The large number of chemical publications resulting from the synthetic effort attests to the contribution the program made to the chemistry of aminothiols.

It was realized that it would be desirable to uncover new classes of active compounds. Toward this end screening of selected compounds outside of the aminoalkylthiol type was carried on but no new classes emerged, even though somewhat over 1500 were tested; the

bulk of this random screening was carried out by the U.S. Air Force Radiation Laboratory with support from the U.S. Army Medical Research and Development Command for the last few years. Late intermediates in certain syntheses were also sometimes tested. Combinations of what were thought to be significant groupings were also tried. Thus, the sodium sulfinate group, $-\text{SO}_2\text{Na}$, conferred special antiradiation properties on the $[-\text{S}(\text{CH}_2)_4\text{SO}_2\text{Na}]$ moiety compared to the unsubstituted moiety $[\text{S}(\text{CH}_2)_3\text{CH}_3]$ when used as a thiol-blocking group. Combining this moiety in the form of a trisulfide (WR 168,643, Table 47) yielded a highly active antiradiation compound that was atypical in that the molecule contained no nitrogen. The theoretical significance and potential utility of this finding have yet to be explored. Other "no-nitrogen" compounds are also active (Table 47). This class of compounds deserves the attention of future investigators. Other classes that have probably not been adequately explored are the amidine and aminoalkylamino derivatives.

The program was originally designed to solve what was believed to be a relatively straightforward problem in medicinal chemistry, *i.e.*, to explore in a logical manner the limits of the chemical lead, to test the best compounds resulting from the exploration in higher species and, after appropriate safety studies, to test the best compounds in man. As it turned out, this simple medicinal chemistry format was not of sufficient sophistication to allow the unequivocal selection of a radioprotective compound with enough of a safety margin to be attractive for full development. The difficulty lay in the fact that neither antiradiation action nor toxicity necessarily progressed in a simple way with logical structural variations but could be highly specific. This finding was more surprising in view of the simplicity of the original lead. Two examples can illustrate the problem. In the simple alkylaminoethylthiosulfuric acids there are three separate peaks of activity as the alkyl chain is lengthened and similarly two peaks of activity in the corresponding thiol series. The second example is furnished by the aminoalkylaminoethyl derivatives where the active and adjacent inactive compounds of the series were studied for a toxic side effect, *viz.*, *alpha* adrenergic blockading activity. Highly specific and reversible *alpha* adrenergic blockade of vascular smooth muscle, but not of intestinal smooth muscle, was dependent upon the number of methylene groups between the amine functions. Parenthetically, it may be mentioned that two of these highly selective *alpha* adrenergic blocking compounds were also shown to repress and reverse induced hemorrhagic shock in three species of animals and to prevent the deleterious hemodynamic effects of otherwise lethal doses of endotoxin; these compounds, 5-amino-pentylaminoethylphosphorothioic acid, WR-2823, and its symmetrical disulfide, WR 149,024, are presently being developed for use in clinical emergencies. The adrenergic selectivity of these thiol

derivatives is to be contrasted with a non-selective *alpha* adrenergic blockading activity of the one-armed nitrogen mustards now used in clinical practice. These *alpha* blockading compounds demonstrated that simple thiols containing equally simple constituents would interact with some but not all physiological thiols and that these interactions could be controlled by relatively distant but simple structural modifications. Thus the program discovered and was at the same time bedeviled by the different physiological effectiveness of these structurally similar compounds although, in a sense, they were designed with the expectation that they would interchange reversibly with the physiological thiols of the active sites or with disulfide bonds. The problem might have been anticipated from the mechanism of action studies of Eldjarn and Pihl (10). Every series that was studied for phenomena other than antiradiation activity (histamine release and hypotension, cardiotoxicity, hypertension, convulsions) suggested the compounds did have specificity in ways that were not anticipated. Although pharmacological specificities did not necessarily correlate with radioprotection, their exploration will be necessary to guide any future development of a compound with appropriate physiological tolerance. Sulfhydryl-dependent functions are of great physiologic importance and the compounds in this program may offer the beginning of a unique approach to selective modification of some of these functions.

With the exceptions noted earlier, this report summarizes the program through 1973 when it was terminated. The most active compounds were generally effective by intraperitoneal administration at a quarter of the highest tolerated dose and, on a weight basis, in the 5-10 mg/kg range. This range is still at least an order of magnitude away from doses employed in conventional therapy but, in turn, is an order of magnitude improvement over the doses required at the time the program started. Most of the compounds were markedly less effective with oral administration and even the most active orally in the mouse were inactive orally in the monkey possibly because of poor absorption. Studies to surmount these difficulties, either by effective formulation or structure design, are needed. For easy reference to compounds that may provide promising areas for future research two special tables are provided: those compounds that were effective (a rating of +) when administered at one quarter of the highest tested dose are listed in Table 48 and those that were effective at 15 mg/kg or below are listed in Table 49.

METHODS

Compounds

The synthetic procedures for all of the compounds that were synthesized under Army support are given in the respective references in the Survey.

Evaluation of Compounds

An adequate description of the test system was usually not included in the chemistry publications. For this reason it is included in this survey.

Female mice of the Walter Reed Bagg Swiss or Inbred Charles River (ICR) strains, 5-6 weeks old and weighing 21-25g, were randomly assigned to treatment groups. An estimation of the toxicity of each compound to be tested for antiradiation activity, *i.e.*, a determination of the approximate LD_{50} (ALD_{50}), was obtained in separate experiments prior to irradiation. Toxicity estimations were based upon animal survival over a ten-day observation period following intraperitoneal or oral administration of each agent in graded doses using 10 mice at each dose level. Adverse symptomatology was noted and, in addition, each mouse was subjected to a post mortem examination. The highest dose of each compound administered for antiradiation testing was about two thirds of the ALD_{50} unless a lower dose was indicated by adverse symptomatology or pathologic changes; the selected doses of each compound were administered 15-30 minutes before exposure to lethal whole body irradiation. →

Compound formulations were freshly prepared for administration prior to use. The compounds were, depending on their solubility, either dissolved in physiological saline solution or were homogenized in a glass tissue grinder in a suspending medium of physiological saline solution containing 0.2% methyl cellulose (4000 centipoise) and 0.4% Tween-80. The suspensions were exposed to an ultrasonic apparatus for approximately two minutes to insure uniform particle size. The pH range of the solutions or suspensions was adjusted to 5-8, if necessary, provided the compound was stable at the adjusted pH.

Irradiation of the mice was performed utilizing either of two sources: 300 KCP GE Maxitron Unit, with radiation factors of 20 ma, HVL 2 mm Cu, TDS 85 cm, dose rate in air 45 r/min or a specially designed Co-60 irradiator, which contained 1200 curies of Co-60, half above and half below the radiation chamber, with a dose rate range from 100r - 50r/min over a five year period.

Forty mice were exposed in a perforated Lucite dish 20 inches in diameter which rotated continuously during exposure. Control mice injected with only the vehicle used for the

particular drug evaluation were irradiated simultaneously with each treated group and thereafter housed jointly eight to a cage.

The mice were given food and water *ad libitum*. The drinking water contained 10-15 ppm of chlorine to suppress the growth of *Pseudomonas aeruginosa*. The principles of laboratory animal care as promulgated by the National Society for Medical Research were observed.

→ Mortality was tabulated for a 30-day period for each individual animal and all data computerized. Under our conditions, approximately 800r x-ray and 1000r Co-60 gamma irradiation were equally lethal (LD-100₃₀), all control animals dying between the tenth and twenty-first days following exposure. *JS/KE*

Molecular Formula

Compounds are listed in the table in molecular formula order, the molecular formula being recorded in accordance with the system used in Chemical Abstracts.

Alkali and alkaline earth metal salts of acids are recorded as the molecular formula of the free acid; other metal salts and chelates are recorded as such, all elements being included in the molecular formula. Ammonium and amine salts of acids are also recorded as the free acids. Acid salts of amines, such as hydrochlorides, are recorded as the free amine. Quaternary, sulfonium and analogous salts are recorded as such.

The molecular formula of a polymer is recorded as that of the monomer and a copolymer as the combination of the monomers on a 1 : 1 basis, thus $(-\text{CH}_2\text{CH}-)_n$ would be found as $\text{C}_4\text{H}_6\text{OS}$ and $(-\text{CH}_2\text{CH}-)_n \cdot (-\text{CH}_2\text{CH}-)_n$ would be found as $\text{C}_{10}\text{H}_{18}\text{N}_2\text{O}_2\text{S}$.

$$\begin{array}{c} \text{SCOCH}_3 \\ | \\ (-\text{CH}_2\text{CH}-)_n \end{array} \cdot \begin{array}{c} \text{CONH}_2 \\ | \\ (-\text{CH}_2\text{CH}-)_n \end{array} \text{SCON}(\text{C}_2\text{H}_5)_2$$

The Walter Reed Number Index will facilitate the finding of a compound in the table if only the Walter Reed number (WR number) is known.

WR Number

The WR (Walter Reed) number is an accession number that is assigned to each unique structure received. Compounds with identical molecular formulas are entered in ascending WR number.

Structure and Configuration

When possible to do so without sacrificing clarity, structures have been drawn linearly, using appropriate parentheses and brackets, in order to save space. Rings have been drawn and aromatic rings are represented with appropriate double bonds.

Compounds containing asymmetric centers are designated by the letters D, L, or DL when the stereoisomer is known; unless specifically so designated it should be assumed that the compound is the racemic mixture. The configuration of sugar derivatives is designated either by Haworth projection formulas or descriptor terms such as *gluco*, *galacto*, etc. *Cis* and *trans* isomers are designated by the appropriate descriptor term.

Although many of the compounds exist as inner salts, e.g., the aminoalkylthiosulfuric acids, they are recorded as non-ionic. The quaternary and sulfonium salts, however, are recorded as a cation and anion.

Salt Form

The numbers in the Salt Form column refer to the corresponding numbers in the table entitled Salts and Other Forms of Compounds Tested; hydrates and solvents are included in this table. The salt form denotes the form in which the compound was received and tested.

Antiradiation Activity

Data for both intraperitoneal (I.P.) and oral (P.O.) administration of compounds are given when available. The efficacy of a compound is measured by its ability to protect mice against a dose of ionizing radiation that would otherwise be lethal, protection being defined as a 30 day survival. The grading of protective effect against fully lethal radiation is expressed according to the following arbitrary scale: 0 to 19% survival = 0; 20-49% survival = $\pm$; 50-100% survival = +. The precision of the test system does not warrant a narrower interpretation of the data. Occasionally compounds were tested using a sublethal dose of radiation in which case protection was defined as a statistically significant increase in the number of treated mice that survived versus the controls. The rating of such a statistically significant increase is indicated by the letter "S". If there is no significant difference when tested at a sublethal radiation the rating given is simply zero, no reference being made to the degree of protection or to the fact that the dose of radiation was sublethal.

After the highest dose of a compound was selected for antiradiation testing, as explained under Methods, lower doses were arbitrarily set by successively reducing each dose by one half. A rating, as explained above, is given for each dose tested but only the highest dose is recorded in the Survey and other tables since the lower doses that were used are obvious. Very early deaths, *i.e.*, at four days or fewer, are attributed to toxicity of the compound, the effect becoming apparent in the presence of the added stress of radiation. Such a toxic effect is indicated by a (T) following the rating symbol. This combined toxic effect is occasionally manifested in the form of survivors at fractional drug doses but none at the top dose. For this reason the data presented always include a rating for one dose below the lowest dose that caused early deaths. The rating system can be illustrated using the data for compound WR-176,241, $\text{H}_2\text{N}(\text{CH}_2\text{OH})_2\text{CH}_2\text{SPO}_3\text{H}_2$, which shows good activity. At a dose of 1000 mg/kg, intraperitoneally, the rating is given as +(T),+,+, $\pm$ which means that 50% or more of the mice survived with a drug dose of 1000 mg/kg but there were some early deaths; 50% or more of the mice survived following doses of 500 mg/kg or 250 mg/kg and between 20% and 49% of the mice survived after a dose of 125 mg/kg. Since no rating was given for a dose below 125 mg/kg it can be assumed that the compound was not tested at that level.

When tested orally at 1000 mg/kg the indicated rating is 0,± which means that there were fewer than 20% survivors at a dose of 1000 mg/kg, whereas, there were between 20% and 49% survivors at a dose of 500 mg/kg. While no early deaths were noted, the increase in the number of survivors at the lower dose, compared to the higher, probably reflects the effect of the combined insults.

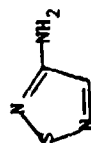

Although expressing the dose of compound on a molar rather than a milligram basis would often allow a more refined comparison of activity, the decision was made to retain the milligram basis because the drug doses were selected on a milligram basis and the actual size of a dose is better appreciated and compared from the practical standpoint. The doses of the compounds tested, as recorded in the table, refer to the free base or non-salt form of the compound.

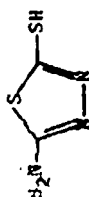

References

The last column in the table gives a reference to the synthesis of the compound, if available, provided the compound was synthesized as part of the Army's Antiradiation Drug Development Program. Primary references, publications and patents, are given if possible. If the synthesis of the compound has not been published, a report is referenced. Generally a report will also be referenced, if the compound is mentioned only in a patent. If the synthetic procedure is not available the source or submitter of the compound is referenced. No attempt has been made to obtain from the open literature the procedures for the synthesis of gift compounds; rather, the source or submitter is acknowledged.

58. G.A. Grant, K.B. Shaw, and R.K. Miller, Defense Research Establishment Ottawa, Report No. 667, December 1972.
59. Minnesota Mining and Manufacturing Company, Final Report, December 1967, Contract No. DA-49-193-MD-2923.
60. Southern Research Institute, Final Report No. 9766-1112-VIII, August 1969, Contract No. DA-49-193-MD-2028.
61. Southern Research Institute Annual Progress Report No. A1098-2133-III, 1971-1972, Contract No. DADA-17-69-C-9033.
62. Southern Research Institute, Annual Report, No. 9235-1112-VII, July 1, 1967-June 30, 1968, Contract No. DA-49-193-MD-2028.
63. Submitted by Indiana University, Contract No. DA-49-193-MD-2096.

64. E. Campaigne and P.K. Nargund, *J. Med. Chem.*, 7, 132 (1964).
65. L. Field, B.J. Sweetman, and M. Bellas, *J. Med. Chem.*, 12, 624 (1969).
66. B.J. Sweetman, M. Bellas and L. Field, *J. Med. Chem.*, 12, 888 (1969).
67. Arthur D. Little, Inc., Final Report, October 1, 1961-December 1, 1962, Contract No. DA-49-193-MD-2071.
68. D.L. Klayman, M.M. Grenan and D.P. Jacobus, *J. Med. Chem.*, 12, 510 (1969).
69. Submitted by Union Carbide Corporation.
70. Esso Research and Engineering Company, Annual Technical Report No. 8, July 1, 1971-June 30, 1972, Contract No. DA-49-193-MD-2608.
71. Esso Research and Engineering Company, Annual Technical Report No. 7, July 1, 1970-June 30, 1971, Contract No. DA-49-193-MD-2608.
72. Rensselaer Polytechnic Institute, Annual Progress Report, September 1, 1962-August 31, 1963, Contract No. DA-49-193-MD-2058.
73. Midwest Research Institute, Final Report, July 1, 1961-December 1965, Contract No. DA-49-193-MD-2174.
74. D.L. Klayman, A. Sinning and G.W.A. Milne, *Acta Chem. Scand.*, 21, 217 (1967).
75. L. Bauer and T.L. Welsh, *J. Org. Chem.*, 26, 1443 (1961).
76. Ohio State University, Final Report, October 1, 1960-September 30, 1965, Contract No. DA-49-193-MD-2104.
77. Wyandotte Chemicals Corporation, Annual and Final Report, July 1, 1963-June 30, 1964, Contract No. DA-49-193-MD-2469.
78. W.O. Foye and J. Mickles, *J. Pharm. Sci.*, 53, 1030 (1964).
79. W.O. Foye and J. Mickles, *J. Progr. Biochem. Pharmacol.*, 1, 152 (Karger, Basel/New York 1965).
80. L. Field, T.F. Parsons and R.R. Crenshaw, *J. Org. Chem.*, 29, 918 (1964).
81. W.O. Foye, R.N. Duvall and J. Mickles, *J. Pharm. Sci.*, 51, 168 (1962).
82. Submitted by Esso Research and Engineering Company, Contract No. DA-49-194-MD-2608.
83. D.L. Klayman and G.W.A. Milne, *J. Org. Chem.*, 31, 2349 (1966).
84. J.R. Piper and T.P. Johnston, *J. Org. Chem.*, 32, 1261 (1967).
85. L. Field and Y.H. Khim, *J. Org. Chem.*, 37, 2710 (1972).
86. Submitted by Arthur D. Little, Inc., Contract No. DA-49-193-MD-2071.

87. Submitted by Rensselaer Polytechnic Institute, Contract No. DA-49-193-MD-2058.
88. Vanderbilt University, Annual Progress Report No. 4, October 1, 1964-September 30, 1965, Contract No. DA-49-193-MD-2030.
89. D.L. Klayman, D. Kenry, R.B. Silverman, J.E. Tomaszewski, and R.J. Shine, *J. Org. Chem.*, 36, 3681 (1971).
90. Submitted by Ohio State University, Contract No. DADA-17-72-C-0273.
91. J.D. Buckman and L. Field, *J. Org. Chem.*, 32, 454 (1967).
92. Parke, Davis & Company, Annual Progress Report No. 5, November, 1967, Contract No. DA-49-193-MD-2306.
93. R.W. Hart, R.E. Gibson, J.D. Chapman, A.P. Reuvers, B.K. Sinha, R.K. Griffith, and D.T. Witiak, *J. Med. Chem.*, 18, 323 (1975).
94. H.F. Herbrandson and R.H. Wood, *J. Med. Chem.*, 12, 620 (1969).
95. B. Buchner and G.C. Curtis, U.S. Patent 3,285,999, November 15, 1966. Assigned to Continental Oil Company.
96. G. Sosnovsky and P. Schneider, *Tetrahedron*, 19, 1313 (1963).
97. L. Bauer, C.L. Bell, K.R. Sandberg, and A.P. Parulkar, *J. Org. Chem.*, 32, 376 (1967).
98. R.D. Westland, M.M. Merz, S.M. Alexander, and L.S. Newton, *J. Med. Chem.*, 15, 1313 (1972).
99. University of Illinois, Final Report, Contract No. DA-49-193-MD-2212.
100. D.T. Witiak, B.K. Sinha, R.R. Ruffolo, and P.N. Patil, *J. Med. Chem.*, 16, 232 (1973).
101. Vanderbilt University, Annual Progress Report No. 3, October 1, 1963-September 30, 1964, Contract No. DA-49-193-MD-2030.
102. R.J. Wineman, M.H. Gollis, J.C. James, and A.M. Pomponi, *J. Org. Chem.*, 27, 4222 (1962).
103. J.C. James, R.J. Wineman and M.H. Gollis, U.S. Patent 3,341,577, September 12, 1967. Assigned to Monsanto Research Corporation.
104. J.C. James, R.J. Wineman and M.H. Gollis, U.S. Patent 3,352,918, November 14, 1967. Assigned to Monsanto Research Corporation.
105. G.R. Handrick and E.R. Atkinson, *J. Med. Chem.*, 9, 558 (1966).
106. L. Bauer and B.K. Ghosh, *J. Org. Chem.*, 30, 4298 (1965).
107. Phillip Petroleum Company, Report for the Period October 1, 1963-January 31, 1965, Contract No. DA-49-193-MD-2069.

108. J.C. James, R.J. Wineman and M.H. Gollis, U.S. Patent 3,462,429, August 19, 1969. Assigned to U.S.A.
109. J.R. Piper, C.R. Stringfellow and T.P. Johnston, *J. Med. Chem.*, 9, 911 (1966).
110. H. Gershon and R. Rodin, *J. Med. Chem.*, 8, 864 (1965).
111. Monsanto Research Corporation, Fifth Annual Progress Report, April 1, 1964-March 31, 1965, Contract No. DA-49-193-MD-2109.
112. Yale University, Annual Progress Report, January 1, 1961-December 31, 1961, Contract No. DA-49-193-MD-2106.
113. Arthur D. Little, Inc., Annual Report, October 1, 1959-October 1, 1960, Contract No. DA-49-193-MD-2071.
114. D.S. Tarbell, D.A. Buckley, P.P. Brownlee, R. Thomas, and J.S. Todd, *J. Org. Chem.*, 29, 3314 (1964).
115. F.I. Carroll, J.D. White and M.E. Wall, *J. Org. Chem.*, 28, 1240 (1963).
116. Southern Research Institute, Annual Progress Report No. 8679-1112-VI, July 1, 1966-June 30, 1967, Contract No. DA-49-193-MD-2028.
117. T.P. Johnston and C.R. Stringfellow, *J. Med. Chem.*, 9, 921 (1966).
118. D.C. Dittmer, O.B. Ramsay and R.E. Spalding, *J. Org. Chem.*, 28, 1273 (1963).
119. University of Illinois, Ph.D. Dissertation, T.T. Conway, 1967, Contract No. DA-49-193-MD-2047.
120. Esso Research and Engineering Company, Annual Technical Report No. 9, July 1, 1972-August 31, 1973, Contract No. DA-49-193-MD-2608.
121. Monsanto Research Corporation, Sixth Annual Progress Report, April 1, 1965-March 31, 1966, Contract No. DA-49-193-MD-2109.
122. Southern Research Institute, Annual Progress Report No. A1098-2133-III, 1971-1972, Contract No. DADA17-69-C-9033.
123. Southern Research Institute, Annual Progress Report No. 7468-1112-IV, July 1, 1964-June 30, 1965, Contract No. DA-49-193-MD-2028.
124. R.D. Westland, J.L. Holmes, B. Green, and J.R. Dice, *J. Med. Chem.*, 11, 824 (1968).
125. Submitted by Yale University, Contract No. DA-49-193-MD-2106.
126. Southern Research Institute, Annual Progress Report No. SORI-KM-73-113 (1972-1973) Contract No. DADA17-69-C-9033.
127. G.C. Curtis and B. Buchner, U.S. Patent No. 3,286,002, November 15, 1966. Assigned to Continental Oil Co.

128. University of New Mexico, Final Report, March 16, 1960-March 15, 1962, Contract No. DA-49-193-MD-2105.
129. Submitted by Massachusetts College of Pharmacy, Contract No. DA-49-193-MD-2029.
130. G.W. Stacy, B.F. Barnett and P.L. Strong, *J. Org. Chem.*, 30, 592 (1965).
131. E. Campaigne and M.C. Wani, *J. Org. Chem.*, 29, 1715 (1964).
132. Midwest Research Institute, Annual Progress Report No. 3, July 1, 1963-October 31, 1964, Contract No. DA-49-193-MD-2174.
133. C.G. Overberger, H. Ringsdorf and N. Weinshenker, *J. Org. Chem.*, 27, 4331 (1962).
134. C.G. Overberger, H. Ringsdorf and B. Avchen, *J. Org. Chem.*, 30, 3088 (1965).
135. T.P. Johnston and A. Gallagher, *J. Org. Chem.*, 29, 2442 (1964).
136. T.P. Johnston and R.D. Elliott, *J. Org. Chem.*, 32, 2344 (1967).
137. D.L. Klayman, J.J. Maul, G.W.A. Milne, *J. Heterocycl. Chem.*, 5, 517 (1968).
138. L. Field and J.D. Buckman, *J. Org. Chem.*, 33, 3865 (1968).
139. A.F. Ferris and B.A. Schutz, *J. Org. Chem.*, 28, 3140 (1963).
140. University of Illinois, Annual Progress Report, April 1, 1967-March 31, 1968, Contract No. DA-49-193-MD-2047.
141. F.I. Carroll, H.M. Dickson and M.E. Wall, *J. Org. Chem.*, 30, 33 (1965).
142. B.J. Sweetman, M.M. Vestling, S.T. Ticaric, P.L. Kelly, and L. Field, *J. Med. Chem.*, 14, 868 (1971).
143. J.R. Piper and T.P. Johnston, *J. Org. Chem.*, 28, 981 (1963).
144. Parke, Davis & Company, Annual Progress Report No. 4. September 1, 1965-August 31, 1966, Contract No. DA-49-193-MD-2306.
145. Esso Research and Engineering Company, Annual Technical Report No. 3, June 1, 1966-May 31, 1967, Contract No. DA-49-193-MD-2608.
146. A.F. Ferris and B.A. Schutz, *J. Org. Chem.*, 29, 201 (1964).
147. Southern Research Institute, Annual Progress Report No. 7468-1112-IV, July 1, 1964-June 30, 1965, Contract No. DA-49-193-MD-2028.
148. Parke, Davis & Company, Annual Progress Report No. 8, September 1, 1969-August 31, 1970, Contract No. DA-49-193-MD-2306.
149. Indiana University, Final Report, October 1, 1960-January 1, 1961, Contract No. DA-49-193-MD-2108.

150. Kansas State University, Final Report, July 1, 1959-July 1, 1963, Contract No. DA-49-193-MD-2026.
151. H.F. Herbrandson and R.H. Wood, *J. Med. Chem.*, 12, 617 (1969).
152. University of California, Final Report, 1965, Contract No. DA-49-193-MD-2145.
153. J.D. Buckman, B.S. Johnson and L. Field, *Can. J. Microbiol.*, 12, 1263 (1966).
154. J.R. Piper and T.P. Johnston, U.S. Patent 3,892,824, July 1, 1975. Assigned to Southern Research Institute.
155. W.O. Foye and R.H. Zaim, *J. Pharm. Sci.*, 53, 906 (1964).
156. T.P. Johnston, C.R. Stringfellow and J.R. Piper, *J. Med. Chem.*, 11, 1256 (1968).
157. Parke, Davis & Company, Annual Progress Report No. 6, September 1, 1967-August 31, 1968, Contract No. DA-49-193-MD-2306.
158. J.R. Piper, L.McC. Rose and T.P. Johnston, *J. Org. Chem.*, 37, 4476 (1972).
159. D. Rosenthal, G. Brandrup, K.H. Davis, Jr., and M.E. Wall, *J. Org. Chem.*, 30, 3689 (1965).
160. University of Illinois, Final Report, May 31, 1965, Contract No. DA-49-193-MD-2212.
161. D.L. Klayman and W.F. Gilmore, *J. Med. Chem.*, 7, 823 (1964).
162. Michigan Chemical Corporation, Final Report, October 26, 1961, Contract No. DA-49-193-MD-2036.
163. S.D. Turk, R.P. Louthan, R.L. Cobb, and C.R. Bresson, *J. Org. Chem.*, 29, 974 (1964).

STRUCTURE-ACTIVITY RELATIONSHIPS

The decision having been made to study the modification of MEA and MFA in an attempt to increase effectiveness and decrease toxicity, compounds were synthesized which involved modification of the amino moiety, the backbone between the N and S atoms and the thiol moiety.

In this S-A discussion an attempt will be made to draw broad conclusions where there seems to be sufficient support from the data. While this will often be difficult and incomplete because of the scattering of structural variations and the nature of the testing, the effort would seem to be justified because such generalization would be useful in a field where thinking is usually centered upon individual compounds. The activities referred to will be those from intraperitoneal administration of the compound unless oral administration is specifically indicated.

The Thiol Blocking Concept

Early in the drug development program the data indicated that an active compound would possess a sulfhydryl or a physiologically potential sulfhydryl group separated by two or three carbon atoms from a basic nitrogen function. Blocking of the thiol group in a way such that it became unavailable metabolically, *e.g.*, as a thioether, resulted in inactive compounds. It also became apparent that the relative activity and toxicity within a series of otherwise identical compounds can be markedly affected by the nature of the sulfhydryl-latentiating group; thus the order of toxicity and activity of one series of compounds may be the complete reverse of another with the identical sulfur-blocking groups. Three such series are shown, by way of illustration, in Tables 1, 2 and 3; other series could be similarly developed. Doses and approximate LD₅₀s (ALD₅₀) are presented on a molar basis to facilitate comparison. In the series of amide derivatives shown in Table 1 the thiol was the least toxic and the phosphorothioate the most toxic whereas in the series of diamines shown in Table 2, the phosphorothioate was the least toxic and the disulfide* the most toxic with the thiol the next most toxic. In comparing the activities of members of the series of Table 1 it is seen that the thiol was most active, effecting good protection at about one fourth of its ALD₅₀ whereas the phosphorothioate gave no protection at nearly one half of its ALD₅₀. With the diamines, on the other hand, Table 2, the phosphorothioate was the most active, giving

*It should be kept in mind that the unblocking of a thiol in the form of a disulfide, unlike the unblocking of other thiol functions, yields two molecules of thiol for each disulfide molecule if the unblocking is a reductive process.

complete protection at less than one third of the ALD_{50} and appreciable protection at about one seventh of the ALD_{50} ; the thiol on the other hand was inactive at one third of its ALD_{50} and the thiosulfuric acid (Bunte salt) was inactive at two thirds of its ALD_{50} . In contrast to the highly polar, water soluble series of diamines, Table 2, where the Bunte salt was relatively non toxic compared to the disulfide, the introduction of the highly lipid solubilizing decyl group produced a series, Table 3, in which the Bunte salt, WR-1607, was the most toxic member of the series, being on the order of 6 times as toxic as the thiol; in contrast, in the amide series, Table 1, the Bunte salt was only about 1.3 times as toxic as the thiol and in the diamine series, Table 2, it was only about one half as toxic. The decyl compound, WR-1607, was however, in contrast to the very polar diamine, WR-9720, Table 2, very active both relative to the ALD_{50} and in the absolute (mg) dose. It was thus necessary to synthesize and test a number of the sulfur-blocked analogs for each promising moiety that was attached to the amino group of MEA. Altogether about 50 different sulfur-blocking moieties were examined in the course of the program but the highest activity was usually found among the thiols, disulfides, thiosulfuric acids or phosphorothioic acids. These classes, therefore, received the most attention in the synthetic effort and necessarily form the basis of the structure-activity analysis.

The data presented above indicate that the mode of action of these compounds is complex. Because of the greater *in vivo* lability of the various thiol-blocked moieties compared to the N-substituted end of the MEA molecule, the blocked thiols have been considered as prodrugs, the blocking group controlling such factors as the rate of *in vivo* release of the active thiol, the toxicity, and membrane passage; thus the blocked thiols were associated with the drug delivery system whereas the N-substituents were associated with modification of the inherent antiradiation properties of MEA. While such a compartmentalization of effects is a gross over-simplification, the concept was useful in the practical program. Substituents on the thiol-blocking group far removed from the actual thiol-blocking bond can also have a marked effect. For example WR-77,548, $CH_3CONHCH_2CH_2SS(CH_2)_3CH_2SO_2H$, gave essentially complete protection at about 1/15th of its ALD_{50} whereas WR-76,844, the corresponding sulfonic acid, $CH_3CONHCH_2CH_2SS(CH_2)_3CH_2SO_3H$, gave only fair protection at two thirds of its ALD_{50} and was inactive at one third of this dose.

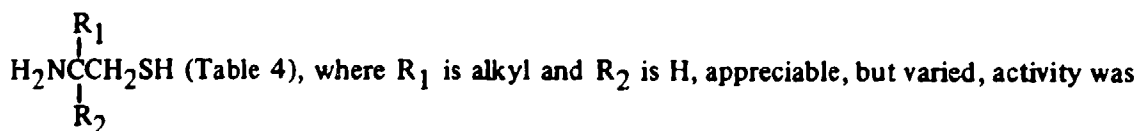

3-Aminopropanethiols and Derivatives

In general, the data indicate that, in the aminoalkylthiol-type compounds, a two carbon chain between N and S confers optimal antiradiation activity. Increasing the chain

length beyond three carbons abolishes activity. With relatively few, but perhaps important, exceptions, discussed below, activity of the 3-aminopropanethiol types was low or non-existent. This generalization has been amply verified by testing numerous compounds in which 3-aminopropanethiol has been substituted both on the nitrogen and on the backbone, including compounds in which vicinal carbons in the backbone have been incorporated in a cycloalkane moiety; one exception, *cis*-2-mercapto-cyclooctylmethylamine, WR-192,526, did have appreciable, but not outstanding activity. The 3-aminopropanethiosulfuric acids, including those with a variety of substitutions, were also inactive. However, when a hydroxy group is inserted in the backbone, *i.e.*, 2-hydroxy-3-aminopropanethiosulfuric acid, a number of the simple *N*-*n*-alkyl derivatives of the hydroxylated form, but not the parent hydroxylated compound, showed activity. There seemed to be no pattern to the activity and the best compound was the *N*-octyl homolog, WR-142,911. The 3-aminopropylphosphorothioates followed the same pattern as the Bunte salts. However, the parent compound, WR-35,978, while inactive at tolerated doses, can be converted to very active derivatives by the introduction of a 2-hydroxy or 2-amino group on the backbone, WR-77,913 and WR-114,391 respectively. The former compound, WR-77,913, was particularly noteworthy. In addition to these modifications, the substitution of certain aminoalkyl groups on the amino group of the parent, *i.e.*, $\text{RNH}(\text{CH}_2)_n\text{NHCH}_2\text{CH}_2\text{CH}_2\text{SPO}_3\text{H}_2$, resulted in very active compounds (Table 39). Finally, there can be activity when the basic nitrogen function is three carbons removed from the sulfur if the basic function is an amidino group (Table 46).

Backbone Substitutions (Tables 4-10)

If the amino function does not terminate a chain in the aminoethanethiols, *i.e.*,

retained when R_1 is not larger than propyl; where R_1 is alkyl and R_2 is methyl, activity was lowered or abolished and when R_1 and R_2 form part of a carbocycle, activity was also abolished. The same generalization can be made for the corresponding thiosulfates (Table 5); however, in this class the compounds were inactive when R_1 is larger than ethyl. The two carbocyclic thiosulfates, WR-2649 and WR-2579, did show some activity as opposed to the corresponding thiols but this activity was at the expense of higher test doses which were used because of the lower toxicity. In general, the toxicity of the thiosulfates was lower than the thiols and comparable to the phosphorothioates (Table 6). The data on the latter class are

very limited but, aside from the greater activity of the parent compound compared to the parents of the other two classes, the trend in activity would seem to be the same.

When the thiol function does not terminate a chain, *i.e.*, $\text{H}_2\text{NCH}_2\overset{\text{R}_1}{\underset{\text{R}_2}{\text{C}}}\text{SH}$ (Table 7),

activity was abolished when R_1 is larger than methyl and R_2 was hydrogen. Stereoisomerism seems to be unimportant. When the thiosulfate group does not terminate a chain, *i.e.*,

$\text{H}_2\text{NCH}_2\overset{\text{R}_1}{\text{C}}\text{HSSO}_3\text{H}$ (Table 8), the compounds were, again, less toxic than the corresponding thiols but activity ended early in the series.

When neither the amino nor the sulfur function terminates the chain, *i.e.*,

$\text{H}_2\text{NCH}\overset{\text{R}_1}{\underset{\text{R}_2}{\text{C}}}\text{SH}$, activity was absent. However, when R_1 and R_2 form part of a carbocycle, *e.g.*, 2-aminocyclobutanethiol, 2-aminocyclopentanethiol, etc., activity was restored. The activity fell off as ring size increased from cyclobutane through cyclohexane; *cis* 2-aminocyclobutanethiol had about the same activity as aminoethanethiol. The *cis* isomer seemed somewhat better than the *trans* in each case. There are not enough thiosulfates of this type to draw conclusions.

Functionalization of the alkyl group R_1 and R_2 in the $\text{H}_2\text{NC}(\text{R}_1\text{R}_2)\text{CH}_2\text{SH}$ series either by hydroxylation or thiolation lead to profound changes in toxicity and reactivity (Table 9). Thus when R_1 is $-\text{CH}_2\text{SH}$, the 1,3-propanedithiols, the compounds were generally quite toxic regardless of the nature of R_2 and more toxic than the corresponding unfunctionalized compounds in the few cases where comparisons can be made. When both R_1 and R_2 are hydroxymethyl, the compound was much superior to the corresponding one where the methyl groups are unsubstituted. The compound with an aminoalkyl group, WR-193,702, was highly active but this type of structure was explored only in the corresponding phosphorothioate series (Table 10). The compounds in the latter group were all highly active and of relatively low toxicity. While there is a paucity of the corresponding functionalized derivatives in the thiosulfuric acid series, a comparison of WR-2389, WR-2917 and WR-176,241, Tables 9 and 10, illustrates what is generally true: the water soluble polyhydroxyalkyl or polyaminoalkyl types are least active when the sulfur-containing function is in the form of a thiosulfuric acid. There are insufficient data of the type $\text{H}_2\text{NCH}_2\text{C}(\text{R}_1\text{R}_2)\text{SH}$ where R_1 and R_2 are functionalized to justify comment.

The *n*-alkylaminoethanethiosulfuric acids, $\text{RNHCH}_2\text{CH}_2\text{SSO}_3\text{H}$, showed an interesting triphasic pattern of activity as R is increased in the homologous series to 18 carbons (Table 11). The first three members of the series, R = methyl, ethyl and propyl were active. The next four, R = C₄ thru C₇ were inactive but activity was again evident in the series when R = C₈ thru C₁₀. With further extension of the series the activity disappeared except for some low activity shown by the R = C₁₃ and R = C₁₄ homologues. This homologous series of *n*-alkylaminoethanethiosulfuric acids progresses from the more water soluble members to the water insoluble; the toxicity increased as the molecular weight increased and reached a maximum in the range of R = C₁₀-C₁₄, after which it diminished. The most active members of the series, other than the first few members, were characterized by a relatively high efficiency in terms of milligrams required for protection when the compounds are administered parenterally. They were inactive when administered orally which suggests that they are not well absorbed. The efficient intraperitoneal activity is compromised somewhat by the relatively high toxicity. A number of the alkylaminoethanethiosulfuric acids have been found to produce a generalized vasoconstriction and myocardial depression in the dog which resulted in hypertension, slowed heart rate and narrowed pulse pressure. In addition, the *n*-decyl homolog (R = C₁₀), WR-1607, was found to possess β -adrenergic blocking action.

In a fair number of examples, with only two exceptions, isomerization of the normal alkyl chain of the alkylaminoethanethiosulfuric acids resulted in retention or enhancement of activity in those cases where the corresponding normal chain was active, *i.e.*, in the octyl-, nonyl-, and decyl- aminothiosulfuric acids (Table 12). In the only example of the isomerization of the undecyl chain, WR-2411, activity was found in contrast to the normal isomer. No activity was seen in compounds where the nitrogen was tertiary, either in the dialkylamino type or when the nitrogen atom was incorporated in a ring. N-acylated compounds were also inactive. The introduction of an alkyl or phenyl group on the backbone of the aminoethanethiosulfuric moiety had no effect on the activity of those compounds that were inactive without such substituents; of the few active compounds that were so modified, WR-1607, WR-258 and WR-3548, activity was abolished.

The corresponding homologous series of *n*-alkylaminoethanethiols, $\text{RNHCH}_2\text{CH}_2\text{SH}$, (Table 11), closely, but not exactly, paralleled the pattern of activity of the Bunte salts. Thus the activity in the short chain homologues does not extend as far in the thiol series as in the Bunte salt series, *i.e.*, R = C₁ versus C₃. In addition, the second peak of activity extends from R = C₈ thru R = C₁₁; further elongation of the chain produced no third peak of low activity as in the Bunte salt series.

As is the case with the alkylaminoethanethiosulfuric acids isomerization of a normal alkyl chain with 7 or fewer carbons in the alkylaminoethanethiol series had no salutary effect (Table 12). Unfortunately there is a paucity of thiols with isomerized alkyl groups containing 8, 9, 10 or 11 carbons for comparison with the thiosulfuric acids. However, the few data that are available suggest that they are not as toxic nor are they as active as the thiols with normal chains. The introduction of an alkyl, hydroxyalkyl, or phenyl on the two-carbon backbone of the aminoethanethiol moiety in the *n*-alkylaminoethanethiols abolished activity. Tertiary aminoethanethiols, either the dialkylamino type or those in which the N atom is a part of a ring were uniformly inactive.

The alkylaminoethylphosphorothioates, as a series, were not studied to the extent of the thiosulfuric acids or thiols. From limited data it would appear that, in their pattern of activity, they were more like the thiosulfuric acids than the thiols. In the few direct comparisons possible in the range of alkyl groups that confer activity, they were, at least, as active or more active than the corresponding thiosulfuric acids. Compound WR-75232, for example, was particularly active.

Relatively few of the alkylaminoethanedisulfides were obtained. The potent disulfide, cystamine, WR-352, was comparable in activity to the corresponding thiol, MEA. As a class there are insufficient data to draw any generalizations.

Phenalkylaminoethanethiols and Derivatives (Tables 13 and 14)

The homologous series of phenalkylaminoethanethiols, (Table 13), $C_6H_5(CH_2)_nNHCH_2CH_2SH$, $n = 0-4$, were consistently more toxic than the corresponding thiosulfuric acids, and, with the exception of WR-3233, had little or no intraperitoneal activity at the doses tested; they were not tested orally. The homologous series, with or without substituents on the phenyl ring, was not carried beyond $n = 4$ because the corresponding thiosulfuric acid series seemed to hold more promise, e.g., WR-2397 and WR-36956 (Table 13) vs WR-2754 and WR-3050 (Table 14) respectively. In the homologous series of unsubstituted phenalkylaminoethanethiosulfuric acids, Table 14, $C_6H_5(CH_2)_nNHCH_2CH_2SSO_3H$, $n = 0-6$, the first three members of the series were inactive but the other four compounds were active. The optimum chain length was $n = 4$ and $n = 5$, both compounds showing good activity. The introduction of methyl or ethyl groups on the phenyl ring of the phenbutyl homolog brought about a dramatic increase in toxicity (10 to 20 times as toxic) with retention of activity at the correspondingly low doses at which the compounds were tested. The introduction of a 4-OCH₃ substituent in the phenyl ring of the phenalkylaminoethanethiosulfuric acids had, in general, a salutary effect on activity, especially notable in the phenbutyl analog. Branching of

the two-carbon spacer between the unsubstituted phenyl ring and the nitrogen of the thiosulfuric acids introduced no activity. No noteworthy activity was found for the relatively few of these Bunte salts that were tested orally. The one that showed the best activity when administered intraperitoneally, WR-3050, was inactive when administered orally.

Hydroxyalkylaminoethanethiols and Derivatives (Tables 15-20)

Monohydroxylation of the alkyl chain of the alkylaminoethanethiols, regardless of the position of the hydroxyl group or of branching of the chain, reduced the toxicity of the compound compared with the unsubstituted alkyl derivative (Table 15). The hydroxyethyl and hydroxypropyl derivatives were active in contrast to the unsubstituted derivatives but were tested at higher doses because of the lower toxicity. Analogs with R groups containing more than 3 carbon atoms and bearing a single hydroxyl, with the strange exception of the 5-hydroxypentyl analog, WR-2469, were inactive. When the nitrogen atom was made tertiary, either by simple alkylation or doubling the hydroxyalkyl moiety, all activity was abolished.

In general when more than one hydroxyl is introduced into the alkyl chain (Table 15) toxicity is further reduced and testing can be done at higher doses. The polyhydroxyalkyl derivatives all gave appreciable activity, WR-2347 being outstanding. The number of possible position isomers is so large compared to the number of compounds tested that it is essentially impossible to generalize. It would appear, nevertheless, in comparing the hydroxy and polyhydroxy derivatives that isomerism does play an appreciable role.

A comparison of the activity of the hydroxyalkyl-substituted derivatives as a function of the sulfur-blocking group can be made only tentatively because there were many more thiols synthesized than disulfides, thiosulfuric acids or phosphorothioic acids and a direct comparison of a series of compounds bearing the same N-alkyl moiety, but having all four sulfur-blocking groups was usually not possible (Tables 16, 17 and 18). However, it does seem clear that, as a class, the hydroxyalkylthiosulfuric acids are the least toxic and the disulfides the most toxic with the thiols and phosphorothioic acids occupying an intermediate position. With respect to activity the phosphorothioates, as a class, would appear to be the most active while the disulfides and thiosulfuric acids are the least active. Interesting too was the di(hydroxyethyl) derivative (WR-4122, $ALD_{50} = 1750$) because of the activity and much lower toxicity compared to the unsubstituted dialkyl analog.

No noteworthy activity was seen in the hydroxyalkyl class of compounds when they were administered orally regardless of the type of thiol blocking. The most active thiol when administered intraperitoneally, WR-2347, was inactive when administered orally.

Simple alkylation of the hydroxyl group of hydroxyethyl-, or 3-hydroxypropylaminoethanethiols, WR-698 or WR-1119, increases toxicity and abolishes activity (Table 19). However, if the alkylating group contains a hydroxyl group, activity is retained with no increase in toxicity. There are too few of the alkoxyalkylaminoethanethiosulfuric acids to draw conclusions with respect to hydroxylation of the O-alkyl group but O-alkylation of the long chain ω -hydroxyalkyl derivatives does apparently increase toxicity compared to the analog with the free hydroxyl group. The cycloalkoxyaminoethanethiols (Table 20), with the exception of the first two compounds, WR-3069 and WR-4111, exhibited fair to good activity over the entire range of structural variations when administered intraperitoneally. About one-half of the active compounds were tested by oral administration and were found to be inactive, without exception.

Phenoxyalkylaminoethanethiols and Derivatives (Tables 21-24)

In the phenoxyalkyl series many more aminoethanethiosulfuric acids (Table 22) were synthesized than were thiols (Table 21) or disulfides (Table 23). Because of this situation, comparisons of the three sulfur-blocking groups has to be tentative. However, when comparisons are possible, the thiosulfuric acids, in general, were the least toxic. When the aryloxy moiety is attached to the nitrogen by a short chain, *i.e.*, 2 or 3 carbons, the compounds were invariably inactive or of very low activity, regardless of the nature of the substituents on the ring. The most active compounds of the thiosulfuric acid series when administered intraperitoneally were found when the insulating methylene chain was 4, 5 or 6 carbons in length ($n = 4,5,6$); the type of substituent on the ring also markedly effected activity. High activity did not carry over to oral administration. There are an insufficient number of compounds in the thiol or disulfide series to extend such a generalization. The thiols were of such modest activity that the activity by oral administration was not investigated. Very few phosphorothioates in this series were synthesized. The unsubstituted phenoxy analogs insulated by 2, or 3 carbons were, like their thiol and thiosulfuric acid counterparts, inactive. Where direct comparison was possible in the aryloxybutyl series, *e.g.*, the 2,6-(CH₃)₂C₆H₃-O(CH₂)₄-, 2-(CH₃)₂CHC₆H₄-O(CH₂)₄- and the 3-(CH₃)₂N-4-CH₃C₆H₃-O(CH₂)₄- analogs, (WR Nos. 117 914, 117 917 and 138 736 respectively), the phosphorothioates were more toxic than the thiosulfuric acids and were inactive. Branching of the insulating chain resulted in inactive compounds as did doubling the aryloxyalkyl moiety on nitrogen so as to make the amine tertiary. Although a few of the compounds in the aryloxybutyl series showed some oral activity, the class, in general, was inactive.

When the aminoethanethiol moiety in a number of the phenoxyalkylaminoethanethiols was tied up as an N-substituted thiazolidine in an attempt to increase oral activity, any intraperitoneal activity that was present in the corresponding thiosulfuric was abolished or greatly diminished and no oral activity was evident (Table 24). A direct comparison of the phenoxyalkylthiazolidines with the pyridyloxyalkylthiazolidines cannot be made because of the presence of different substituents on the pyridyl and phenyl rings.

Cycloalkylalkylaminoethanethiols and Derivatives (Tables 25-28)

Only a few compounds were synthesized with carbocyclic rings larger than seven members in the cycloalkylalkylaminoethanethiosulfuric acid series. For normal alkyl spacers of 3, 4, 5, or 6 carbons, toxicity increases as the ring size is increased from 4 to 7 carbons (Table 25). For any given ring size from 4 to 7 carbons, there is a point where the compounds become appreciably more toxic as the length of the normal spacer increases. This point is reached sooner as the size of the ring increases. The most active compounds with unbranched alkyl spacers were clustered in the area of spacers of 4, 5, and 6 carbons and rings of 4, 5 or 6 carbons. Branching of the spacer chain between the cycloalkyl moiety and the nitrogen atom can bring about a marked change in effectiveness and toxicity; compare, for example, WR-2571 with WR-3562; WR-2942 with WR-6136 and WR-7466; and WR-2691 and WR-6403 with WR-6400 (Table 24). Thus the antiradiation activity would seem to depend to some extent upon the total number of carbon atoms in the spacer rather than entirely upon the distance between the ring and nitrogen. Although there are little data, there is the suggestion that the isomerism of the spacing group when both distance and total number of carbons is held constant may play a role; compare, *e.g.*, WR-6136, 7466 and WR-7467.

Most of the cycloalkylalkylaminoethanethiosulfuric acids that were tested by oral administration were inactive and those that were active were only fair at best even when administered at a relatively high dose (Table 25). Oral data did not correlate well with that obtained from intraperitoneal administration.

There were not as many cycloalkylalkylaminoethanethiols synthesized as there were the corresponding thiosulfuric acids. In general, the former were more toxic and less active than the latter. There were not enough of the disulfides or phosphorothioates synthesized to allow generalizations to be made. Intraperitoneal data for these classes are tabulated in Tables 26, 27 and 28.

Heteroalkylaminoethanethiols and Derivatives

Regardless of the type of sulfur blocking, *i.e.*, aminoethane-thiols, -thiosulfuric acids, -phosphorothioates or -disulfides, compounds representing a variety of heterocycles attached directly or through short alkyl chains to the nitrogen atom of the aminoethyl moiety, with attachment involving either a carbon or the hetero atom of the heterocycle, showed little or no activity in general. There were a few exceptions which showed moderate activity but no explanation or correlation was apparent; note, for example, 3-piperidinylmethylaminoethane phosphorothioate, WR 176,256, morpholinoethyldisulfide, WR 177,475 and 2-quinoxalinylaminoethanethiosulfuric acid, WR 176,606.

Pyridyl- and quinolyloxyalkylaminoethanethiols and Derivatives (Tables 29-31)

Derivatives of the 2-aminoethanethiol-type compounds in which a 2-pyridyloxyalkyl or 2-quinolyloxyalkyl group was attached to the nitrogen proved to be an interesting and active series of compounds.

In a series of 2-pyridyloxyalkylaminoethanethiosulfuric acids (Table 29), the length of the alkyl spacer as well as the nature and position of the ring substituent had a marked effect on activity. A chain of 5 carbon atoms with a bromo or chloro group in the 5 or 3,5 positions of the pyridine moiety resulted in the best intraperitoneal activity. The effect of the position of the ring substituent can be appreciated, for example, from a comparison of WR 43,900 with WR 50,480 and WR 85,565 with WR 94,533. With one exception, WR 138,412, all of the Bunte salts that were tested orally were inactive.

The 2-quinolinyloxyalkylaminoethanethiosulfuric acids (Table 30) also proved to be an active series of compounds when administered intraperitoneally. In this series a 3-carbon spacer conferred the greatest activity although it should be noted that only one compound with a 4-carbon spacer was tested. The pentyl ethers were, with one exception, inactive. The unsubstituted quinolyl analog with a propyl spacer was quite active in contrast to the corresponding pyridyl analog. Methyl substituents on the ring increased activity but there was no evidence that the presence of halogen on the ring, unlike the corresponding pyridyl series, was salutary. Attachment of the ether chain at the 4, 5 or 8 positions yielded ineffective compounds; compare WR 106,156 with WR 36,955, WR 25,930 with WR 9463. The unsubstituted 1-isoquinolyl derivative, WR 117,932, isomeric with the active quinolyl derivative, WR 106,156, was inactive. As with the pyridyl ethers, the quinolyl ethers were also ineffective when administered orally.

In contrast to the Bunte salts, the best of the thiols in the 2-pyridyl ether series showed only moderate activity when administered intraperitoneally and even less activity when

administered orally (Table 31). Although data are limited it would appear that a spacer of at least 5 carbons in the side chain is necessary before activity appears. Relatively few of the 2-quinolyloxyalkylaminoethanethiols were prepared and none with appropriate ring substituents or alkyl spacers so that comparisons cannot be made.

2-[(3-Thiazolidinylalkyl)oxy]pyridines and Quinolines (Tables 32 and 33)

Blocking the aminoethanethiol moiety of the 2-pyridyl ethers by incorporation in a thiazolidine gave a series of compounds with only moderate activity when administered intraperitoneally; they were comparable in activity in general to the corresponding thiols but less active than the Bunte salts, with ALD_{50} 's generally higher than either of these classes (Table 32). The outstanding characteristic of the class was the almost universal activity of the compounds when administered orally and the remarkably high activity of certain of the compounds. Although the oral doses of the compounds tested were larger in terms of mg/kg than were the parenteral, they were approximately comparable to the latter when related to the ALD_{50} . The series exhibited oral activity over a range of spacers from 3 to 7 ($n = 3-7$); the 5-halo-2-pyridyl ethers with spacers of 5 and 6 carbons showed the greatest oral activity. In contrast to the pyridyl series, blocking the aminoethanethiol moiety as a thiazolidine in the 2-quinolyloxyalkyl derivatives yielded a series of compounds which, for the most part was inactive, and in which the best representatives showed only moderate activity regardless of the route of administration (Table 33).

2-[(3-Thiazolidinylalkyl)thio]pyridines (Table 34)

The phenomenon of the good oral activity shown by the pyridyl ethers when the aminoethanethiol moiety was incorporated in a thiazolidine was also apparent in the corresponding thio ethers, *i.e.*, the 2-[(3-thiazolidinylalkyl)thio]pyridines. Syntheses were confined to the halopyridyl derivatives because of the concentration of activity in similarly substituted pyridyl ethers. In the series of pyridyl thio ethers the greatest activity was obtained with an alkyl spacer of 5-7 carbons ($n = 5-7$) when the compounds were administered intraperitoneally (Table 34). The most effective range of spacers appeared to be somewhat greater with oral administration ($n = 5-8$) (Table 34). It is also apparent that, in a number of cases, the oral activity of the compound surpassed the parenteral at equal fractions of the respective ALD_{50} 's. Relatively few of the corresponding quinolythio ethers were synthesized so that comparisons cannot be made. However, it is of interest that the only activity uncovered in the latter quinoline derivatives was in those compounds in which the quinoline ring was unsubstituted.

A series of 3-[(alkylthio)alkyl]thiazolidines (Table 35) were synthesized in which m and n were varied. The degree of activity of the compounds when administered intraperitoneally or orally was only moderate and variable depending upon the size of m and n . The best activity in general, was shown by those compounds in which $m + n = 9, 10$ or 11 , although there were exceptions to this conclusion when m or $n < 4$. The noteworthy feature of the series is the fact that any activity shown when administered intraperitoneally generally carried over when the compounds were administered orally. The best compounds in the series when administered orally were WR 157,311 and WR 134,783. The contribution of the sulfur interruption of the chain is impossible to ascertain since an insufficient number of the simple 3-alkylthiazolidines were synthesized and tested. Data for the compound 3-octylthiazolidine, WR 2949, are: ALD_{50} , IP, 150 mg/kg; 50 mg/kg dose IP rated +, $\pm$; ALD_{50} , PO, 700 mg/kg, 300 mg/kg dose PO rated +, +, $\pm$. For 3-decylthiazolidine, WR 2950, the data are: ALD_{50} , IP 75 mg/kg, 50 mg/kg dose IP rated +(T), +, 0; ALD_{50} , PO, 550 mg/kg, 100 mg dose rated +. The activity of these two 3-alkylthiazolidines, both intraperitoneally and orally, suggests that the introduction of sulfur in the chain makes little difference. The oral activity of WR 2949 and WR 2950 stands in contrast to the lack of oral activity of the corresponding derivatives when the sulfur of the aminoethanethiol moiety is present as the thiol itself (see below) or blocked as the thiosulfate, although the latter compounds were highly effective intraperitoneally. Oxygen analogs of the sulfur interrupted chains were not explored to any appreciable extent. The oxygen analog of the very active WR 134,783, (Table 35), viz., WR 158,494, was appreciably less active, both IP and PO, than WR 134,783.

Thus, as just discussed, the blocking of a thiol by incorporation of the aminoethanethiol moiety in a thiazolidine can, in certain series, result in active compounds when the compounds are administered intraperitoneally and the activity can carry over, and sometimes be enhanced, when the compounds are administered orally. The octyl homolog, $CH_3(CH_2)_7NHCH_2CH_2SH$, WR 230, is about twice as toxic as the corresponding 3-(n-octyl)thiazolidine, WR 2949, by intraperitoneal administration, but no more active. Orally the thiol is 3-4 times as toxic as the thiazolidine and is inactive; the thiazolidine, in contrast, has excellent activity. The same type of relationship can be seen when comparing the n-decyl-thiol and -thiazolidine analogs, WR 228 and WR 2950 respectively. Unfortunately the thiazolidines corresponding to thiols with other good N-substituents, e.g., WR 2529, WR 2753, WR 2347 and WR 1065 were not synthesized but their synthesis and testing is certainly indicated. In investigating

new compounds it would be worth the effort to synthesize and test the corresponding thiazolidine if the thiol or a derivative with a blocked thiol proved to have appreciable intraperitoneal activity, regardless of its oral activity.

Aminoalkylaminoethanethiols and Derivatives (Tables 36 and 37)

Data from the testing of N-substituted derivatives of the aminoalkylaminoethanethiols and -phosphorothioates [$R_1R_2N(CH_2)_nNHCH_2CH_2SY$, $Y = H, PO_3H_2$] are shown in Tables 36 and 37. The synthesis of such derivatives was confined mostly to the thiols ($Y = H$) and the phosphorothioates ($Y = PO_3H_2$); relatively few of the corresponding disulfides [$Y = SCH_2CH_2NH(CH_2)_nNR_1R_2$] were synthesized and none showed remarkable activity. Not nearly as many thiosulfuric acids were synthesized as were the thiols and phosphorothioates; those thiosulfuric acids that were synthesized were less toxic than the thiols but were uniformly inactive by intraperitoneal administration, even those corresponding to the very active phosphorothioate congeners. They were not tested by oral administration and have not been tabulated. Compounds in which the distal nitrogen is incorporated in a heterocycle were essentially devoid of activity, regardless of the type of sulfur blocking, and have been omitted from Tables 36 and 37. Most of the other derivatives where R_1 is an alkyl group substituted with such groups as hydroxy, polyhydroxy, amino, hetero, alkyloxy, alkylthio, cyano, carboalkoxy and aryl are included in the table despite the fact that such inclusion makes the table replete with negative data. However, the fact that the best compounds in this class were as good or better than any that emerged from the program makes the scope of the structural types investigated and the comparison of structures the more important and interesting, and justifies the plethora of negative data.

The thiols, $R_1R_2N(CH_2)_nNHCH_2CH_2SY$, ($Y = H$), (Table 36), were, as a class, less active than the phosphorothioates ($Y = PO_3H_2$), (Table 37), and had lower ALD_{50} s. Substitution of alkyl groups larger than methyl ($R_1 > CH_3$) on the distal N of the thiols abolished activity and the best activity was seen when this N was unsubstituted. Alicyclic or terpenoid groups on the distal N also abolished activity. Activity peaked when the nitrogen atoms were separated by a chain of 3 carbon atoms ($n = 3$). The number of thiols tested orally was limited but, for those tested, oral activity was consistently lower than intraperitoneal activity. The introduction of a hydroxyl group on the terminal ethyl group of the thiols WR 6364 and WR 6365, (Table 36), decreased toxicity so that activity was evident in these derivatives, WR 1751 and WR 2153, when tested at the higher tolerated doses. Based upon a limited number of examples, the introduction of hydroxyl substituents on R_1 when R_1 is larger than ethyl ($R_1 > C_2H_5$) had little or no effect with respect to activity. Branching on a

3-carbon chain separating the nitrogens, WR 156,788 and WR 157,529, resulted in the retention of appreciable activity but the introduction of a hydroxyl on this chain, WR 1783, abolished activity.

The aminoalkylaminoethylphosphorothioates, (Table 37), as a class, include the most active and most promising of the antiradiation agents synthesized. This class of compounds was more active and had higher ALD_{50} s than the corresponding class of thiols. Highest activity was obtained when the distal nitrogen is unsubstituted or has only a methyl substitution; unlike the congeneric thiols, some activity was retained with alkyl groups slightly larger than methyl. Large hydrocarbon moieties such as cycloalkyl or terpenoid substituted on the distal N abolished activity. Peak activity, as with the thiols, was seen when there is a chain of 3 carbons between the nitrogen atoms ($n = 3$) but the base of activity was broader and the peak was not nearly as well defined as in the case of the thiols. Good activity was retained when the 3-carbon connecting chain between the nitrogen atoms is branched or when, in contrast to the thiols, it is hydroxylated (WR 151,325). Replacement of the terminal amino group with a guanidino group also resulted in active, but somewhat more toxic, compounds, so that the therapeutic index seems unfavorable. Only a few of this type were made. Although the best compounds of this class showed activity when administered orally, the degree of activity was much less than when administered intraperitoneally, suggesting limited absorption.

Aminoalkylaminopropanethiols and Derivatives (Tables 38 and 39)

Derivatives of the aminoalkylaminopropanethiols, $R_1R_2NH(CH_2)_nNHCH_2CH_2CH_2SY$, were not extensively investigated. For the most part, synthetic efforts were confined to the thiols ($Y = H$) (Table 38) and the phosphorothioates ($Y = PO_3H_2$) (Table 39). The latter derivatives, unlike the simple derivatives of aminopropanethiols, showed excellent intraperitoneal activity when $n = 2$ or 3 , $R = H$ or CH_3 , and $Y = PO_3H_2$ (Table 39) and also when $n = 3$, $R = CH_3$, and $Y = H$ (Table 38). When administered orally the activity of these same compounds was less than when administered intraperitoneally, but was still quite good. Unfortunately, a direct comparison of several of the most active phosphorothioates with the corresponding thiols is not possible. It is interesting that the corresponding guanidino derivative, WR 190,222, (Table 39), was also very active when administered intraperitoneally but not when administered orally. Extension of the length of the chain connecting the nitrogens beyond 3 carbons, *i.e.*, $n > 3$, in the phosphorothioates abolished activity and the same was true for the derivatives of 2-hydroxy-3-aminopropylphosphorothioate, $R_1R_2N(CH_2)_nNHCH_2CHOHCH_2SPO_3H_2$. The latter compound when $R_1 = R_2 = H$ and $n = 3$

(WR 142,489) is quite active by intraperitoneal administration but inactive by oral administration; this is in contrast to corresponding deshydroxy phosphorothioate, WR 44,923, which retains good oral activity. The aminoalkylaminopropanephosphorothioates may deserve additional attention.

It would appear, therefore, that the activities of the most active phosphorothioates in the ethyl or propyl series were comparable, *i.e.*, in the series $\text{RNH}(\text{CH}_2)_n\text{NH}(\text{CH}_2)_m\text{SPO}_3\text{H}_2$ when $\text{R} = \text{H}$ or CH_3 and $n = 2, 3$ or $\text{CH}_2\text{CHOHCH}_2$, the activity of compounds where $m = 2$ was approximately the same as those where $m = 3$.

N,N'-bridged-aminoethanethiols and Derivatives

When two aminoethanethiol molecules were joined through their respective nitrogen atoms by a variety of bridges, the resulting compounds, with few exceptions, were inactive and are not tabulated. Thus only two compounds in a series of N,N'-polymethylene-bridged 2-aminoethanethiols, $\text{HSCH}_2\text{CH}_2\text{NH}(\text{CH}_2)_n\text{NHCH}_2\text{CH}_2\text{SH}$, $n = 2-12$ (the heptylene-bridged homolog, $n = 7$, was not synthesized) showed even moderate activity, *viz.*, those in which $n = 3$ and 4, WR 2665 and WK 2209, respectively; hydroxylation of these bridges, WR 1901 and WR 342, reduced but did not abolish activity. Compounds with other bridges such as 1,4-xylylene, butenylene, branched alkylene, polyether and hydroxyether were ineffective. Although all of the corresponding thiosulfuric acids, on a one-to-one basis were not synthesized, there was a good representation and none showed any activity, including the two that showed activity as thiols. Synthesis of the corresponding bridged phosphorothioates was confined principally to those compounds with alkylene bridges. Interestingly, the two bridges that conferred activity in the thiol series were the same ones that appeared in the active phosphorothioates, *viz.*, $n = 3$ and 4, WR 3694 and WR 4431. These phosphorothioates were, however, considerably more active than the corresponding thiols. As in the thiol series, the analog with a hydroxypropylene bridge, WR 179,212, was also active but less so than the analog with an unsubstituted bridge. The above comparisons again point to the validity of the generalization that, in a given series of highly polar, water-soluble compounds, the phosphorothioates are usually the most active and the thiosulfuric acids the least, with the thiols occupying an intermediate position; toxicities usually follow the reverse order.

N,N'-polymethylene-bridged 3-aminopropanethiol Derivatives

A series of N,N'-polymethylene-bridged 3-aminopropanethiosulfuric acids, $\text{HO}_3\text{SSCH}_2\text{CH}_2\text{CH}_2\text{NH}(\text{CH}_2)_n\text{NHCH}_2\text{CH}_2\text{CH}_2\text{SSO}_3\text{H}$, $n = 3-10$, were completely inactive. The

corresponding series of phosphorothioates, $n = 2-5$ and $7-10$, were also completely inactive. These negative data have not been tabulated. The corresponding thiols were not synthesized.

Mercaptoacetamidines and Derivatives (Tables 40-46)

The synthesis of the acetamidine derivatives was confined largely to those in which the sulfur was blocked as a thiosulfuric acid or as a disulfide. The parent compounds, *i.e.*, those with no substitution on the nitrogen atom, were very active both by intraperitoneal and oral administration regardless of the type of sulfur blocking (Table 40). Compared to the corresponding aminoethyl analogs, the amidines are more efficient but also more toxic.

The simple N-alkylamidine derivatives were synthesized only as the thiosulfuric acids (Table 41). There was a smattering of activity but this was generally of a low order. Compound WR 166,823 was the most active of this group. The *n*-nonyl and *n*-decyl derivatives, WR 2706 and WR 2608 respectively, were quite toxic. Introduction of a hydroxyl group on the short chain analogs brought about no significant improvement.

The synthesis of N-aryl-, N-arylalkyl- and N-substituted-arylalkylamidine derivatives was also, almost exclusively, confined to the thiosulfuric acids (Table 42). A number of these thiosulfuric acids showed activity with intraperitoneal administration ranging from poor to fair but none of the compounds was outstanding. Those that were tested orally were inactive. The best compound was the N-(2-naphthyl) derivative as the disulfide, WR 199,737.

A small number of N-phenoxyalkyl- and N-phenalkyloxyalkylamidine derivatives, along with some thio analogs, were synthesized, almost exclusively in the form of thiosulfuric acids (Table 43). Several of these compounds exhibited good activity when administered intraperitoneally but were definitely less active administered orally. Thus the interruption of the alkyl chain in the N-phenalkyl derivatives by oxygen or sulfur decreased toxicity compared to the compounds with uninterrupted chains of equivalent length, *e.g.*, WR 37,720 and WR 60,237, (Table 43), compared to WR 3856, (Table 42), etc.; it would be of interest to synthesize and test a few 2-naphthyloxyalkyl analogs. The pronounced increase in activity brought about by the introduction of a methyl group on the phenyl ring, WR 8312 vs WR 32,379 is also noteworthy.

Synthesis of the N-cycloalkyl- and N-cycloalkylalkylamidine derivatives was also confined mostly to the thiosulfuric acids and disulfides (Tables 44 and 45); the few thiols and phosphorothioates that were synthesized are included in Tables 44 and 45 respectively. When the compounds were administered intraperitoneally, fair to good activity was generally obtained with both the disulfides and thiosulfuric acids. When administered orally the disulfides were, as a rule, more active and more efficient. There seemed to be no discernible trend in

activity as a function of ring size or chain length. Most of the compounds had a high $ALD_{50}(PO)/ALD_{50}(IP)$ ratio.

The N-(1-adamantyl-) and N-(1-adamantylalkyl)-amidine derivatives, as disulfides (Table 45), were characterized by low intraperitoneal ALD_{50} 's and high $ALD_{50}(PO)/ALD_{50}(IP)$ ratios. Although they are, as a class, inherently active, as shown by their oral effectiveness, no intraperitoneal activity was evident when the alkyl chain was longer than 2 carbon atoms because of the necessity of testing at such low drug doses. The relatively high oral ALD_{50} 's may indicate limited absorption. In general, as a class, the compounds showed fair to good oral activity although toxicity, as evidenced by early deaths, was prevalent. The corresponding thiosulfuric acids were also marked by a high $ALD_{50}(PO)/ALD_{50}(IP)$ ratio. With the exception of the parent N-(1-adamantyl) and N-(1-adamantyl)methyl derivatives there was little or no activity when the thiosulfates were administered intraperitoneally and, with one exception, WR 201,730, no activity when they were given orally, even though some of the doses administered were quite large. Only a few of the 2-adamantyl isomers were synthesized; as disulfides they were at least as active and possibly more active than their corresponding 1-adamantyl isomers both by intraperitoneal and oral administration. The limited data also suggest that the 2-adamantyl isomers, as thiosulfuric acids, may be superior to the 1-adamantyl isomers when administered intraperitoneally; however, when delivered orally they are inactive. As with the 1-adamantyl derivatives, the 2-adamantyl derivatives also show a marked difference between the oral and intraperitoneal ALD_{50} 's. In the few compounds that were made with a sulfur-interrupted alkyl chain (Table 45), the activity of the disulfides was at least equal to the corresponding analog with a non-interrupted chain both by the oral and intraperitoneal routes of administration. A limited number of derivatives with oxygen-interrupted chains as well as sulfur-interrupted were synthesized as thiosulfuric acids. These compounds generally had higher ALD_{50} 's than the compounds with uninterrupted chains of equivalent length. Some of these had fair to good activity intraperitoneally but showed little or no activity orally, as did their counterparts with non-interrupted chains. The amidine derivatives containing N-terpenoid moieties showed fair to good activity in both the disulfide and thiosulfuric acid series when administered intraperitoneally (Tables 44 and 45). In the case of the disulfides the activity carried over to oral administration; however, with the exception of the 2-bornyl analog, WR 92,973, there was little or no activity when the Bunte salts were given orally.

Unlike the simple, unsubstituted aminoalkylthiols and thio derivatives, in which the activity is essentially abolished if the alkyl chain connecting the N and S atoms is extended beyond 2 carbon atoms, the amidines with longer chains retain appreciable activity when

the compound is administered either intraperitoneally or orally (Table 46). The higher homologs are less efficient than the lower on a mg/kg basis but the ALD_{50} 's are appreciably higher.

The synthesis of N-heterocyclic alkyl amidine derivatives was confined largely to the thiosulfuric acids; the alkyl chains joining the heterocycle to the amidine moiety varied from 1 to 3 carbons in length. In general, these compounds were disappointing and not tabulated. Included in the compounds tested were the following heterocyclic moieties: 2-furylmethyl and -ethyl; 2-tetrahydrofurylmethyl; 2-thienylmethyl and -ethyl; 2-, 3- and 4-pyridylmethyl and 2- and 4-pyridylethyl, 2-benzimidazolylethyl, 3-indolylethyl and -propyl and 2-imidazolidinone-2-yl ethyl. All of the pyridyl analogs were inactive as were the 2-furylmethyl, the 2-tetrahydrofurylmethyl, the 3-indolylpropyl and the 2-imidazolidinone-2-yl ethyl analogs. The other compounds were active at the + level only at the highest tested doses. The best compound of the group was the 3-indolylethyl analog, WR 33,762. The 2-benzimidazolylethyl analog showed comparable activity as the thiosulfuric acid, thiol or phosphorothioate.

Guanidinoalkylthiols and Derivatives

The guanidinoalkylthiol derivatives, $RNHC(=NH)N(R_1)(CH_2)_nSY$, where $Y = H, SO_3H$, or $S(CH_2)_nN(R_1)C(=NH)NHR$, showed little or no activity and, as a class, were uninteresting and not tabulated. Simple phosphorothioates were not prepared. All of the parent compounds, i.e., $R = R_1 = H$, $n = 2$ or 3 , and $Y = H, SO_3H$ or $S(CH_2)_nN(R_1)C(=NH)NHR$, with the exception of the guanidinopropyl disulfide, were active only at the highest drug dose administered. When R or R_1 was alkyl the activity was reduced or abolished. It is interesting that the parent compounds $H_2NC(=NH)NH(CH_2)_nSH$, $n = 2$ or 3 , (WR 1574 and WR 2022 respectively) which are generally regarded as the biologically active forms, respectively, of the isothiuronium compounds $H_2N(CH_2)_nSC(=NH)NH$ (AET, $n = 2$, WR 298), (APT, $n = 3$, WR 215), were much less active than the latter compounds. The thiocarbonates corresponding to the parent thiols, i.e., $R = R_1 = H$, $n = 2$ or 3 and $Y = C(=S)SH$ (WR 783 and WR 1479 respectively) were also active, but no more so than the parents.

No-nitrogen Thiols and Derivatives (Table 47)

Thiols, or derivatives, which contain no amino group in the molecule, had shown little or no activity in animals as a class and, therefore, had not been pursued in the antiradiation drug development program. In the course of the synthetic program, however, a small number of such compounds became available and some showed activity comparable to the amino-thiols (Table 47). WR 168,643, a bis-sodium sulfinate trisulfide, was outstanding, both when administered intraperitoneally or orally. Compounds that contain a thiol group or thiol

derivative that can be bioactivated but contain no amino function would seem to have great theoretical importance with respect to mode of action. Since this area has been little investigated it would be worthy of further investigation.
