20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

Certain chemical heat stabilizers provided a significant reduction in heat buildup to various experimental track pad vulcanizates while others provided a significant improvement in tear resistance at 250°F. Although the resistance to heat buildup through the use of wire cloth may be improved in some cases the use of wire cloth in track pads is not feasible because of the chunking and delamination problems associated with its use under dynamic conditions. Blending natural or synthetic natural rubber with SBR 1500, Stereon 750, HYTRANS or SBR/polybutadiene improved the resistance to abrasion,

20. ABSTRACT

tear, and crack growth in most cases. An EPDM/pale crepe blended vulcanizate had significantly improved resistance to abrasion and crack growth when compared to a vulcanizate prepared from EPDM only, but tear resistance was poorer. Blending Stereon 750 or HYTRANS elastomers with fast-curing EPDM and brominated butyl provided no significant improvement in resistance to tear, abrasion, or crack growth when compared to the originally developed Stereon 750 and HYTRANS base compounds. The addition of Santoweb D fibers to various experimental track pad compounds had an adverse effect on the resistance to crack growth.

A summary is included of the efforts of the past 13 years in attempting to improve the wear resistance of rubber track pads. The average service life of pads was approximately 1200-2000 miles when this work was begun. On the basis of service tests conducted on experimental compounds developed during this study, it is reasonably certain that a 3500 mile pad is now a reality.

TABULAR DATA

OBJECTIVE:

The object of this work was to develop a rubber pad for tracked vehicles that would provide reliable service for 5000 miles of vehicle operation.

BACKGROUND:

For the past 13 years, the Research Directorate at Rock Island Arsenal has been involved in funded programs to improve the wear resistance of rubber tank track pads. The studies began in FY63 and have been continuous since that time. Particular emphasis was placed on the improvement of the wear resistance of rubber pads for the T142 and T130 tracks since unit procurement for these tracks is, by far, the largest for track currently in use. The T142 track is used on the M48-and M60-series tanks, and the T130 track is used on the M113 personnel carrier. The operating life and reliability of the T142 track, developed to replace the T97E2 track, is limited to approximately 2000 miles because of the limitations of the rubber components. While the metal track remains operational for 5000 miles or more, the average life of the rubber pads is seldom more than 2000 miles. A rubber track pad that would match the operational life of the metallic track is highly desirable and would result in increased reliability and reduced maintenance, and in a tremendous cost savings in the purchase of replacement pads. Commercially available track pads fabricated from SBR fall far short of the objective. Past efforts of this laboratory[1-10] have been directed toward (1) the development of pads

that would match the operational life of the metal track and (2) the development of a laboratory test or tests that could be used in the prediction of the wear resistance of experimental track pad compounds without resorting to costly and time consuming service tests. Significant progress has been made in both areas. Experimental track pads based on stereospecific SBR (Stereon 750), SBR/polybutadiene blends (Philprene 1609/Cis-4 1350 (or Cis-4 1351), Ameripol 1834/Ameripol CB 1352) and alfin catalyzed copolymers of butadiene/styrene and butadiene/isoprene (HYTRANS) have exhibited a 50 percent or greater improvement in tread wear during service tests when compared to commercial SBR pads. The service testing of commercially prepared pilot lots of pads based on stereospecific SBR and SBR/polybutadiene blends has confirmed this improvement in tread wear. The uncertainty regarding the future commercial availibility of the alfin catalyzed copolymers of butadiene/isoprene and butadiene/styrene has precluded the preparation of pilot lots of pads based on these elastomers. Correlation was found between service test wear ratings and laboratory test data obtained for tear strength, resistance to crack growth, and abrasion resistance. This report covers work done on the improvement of the wear resistance of rubber track pads since issuance of the previous report[10] plus a summary of all work done on this problem since the initial investigation began in FY63.

APPROACH:

Rubber compounds designed for initial laboratory evaluation were mixed on a 12-inch rubber mill. Tensile strength, elongation, and modulus were determined at ambient and elevated temperatures by use of a Scott Model L-6 rubber tensile tester equipped with a Scott Model HTO hot tensile oven and autographic recorder-controller. Each dumbbell specimen was placed in the grips of the tester and conditioned for six minutes at the elevated temperature before being tested. All other physical properties were determined by ASTM procedures where applicable. Physical properties of experimental compounds were compared with those of the Research Directorate SBR control compound which has given wear ratings similar to those of commercial SBR compounds in numerous service tests.

A Number 1 Banbury mixer was used to mix all compounds selected for the preparation of experimental track pads. The Banbury mixed compound was transferred to a 30-inch mill for additional mixing and sheeting-out. The cooled stock was later transferred to an 18-inch mill for warmup and for sheeting-out to the desired thickness for preparation of track pad preforms from rolled stock.

---

10 Bergstrom, Ibid.

The following surface preparations were made on the track pad metal backup plates (inserts) and on the ASTM D429-68 steel test panels prior to vulcanization-bonding to the rubber stocks: degreasing, glass beadblasting, solvent-wiping, brush application of bonding agent, and drying.

Service tests of experimental track pads were arranged through the U.S. Army Tank-Automotive Command (TACOM), Warren, Michigan.

The following wear (durability) rating was used to compare the performance of the rubber track pads tested:

$$\text{Volume Wear Rating} = \frac{\text{Average volume loss of commercial SBR control pads}}{\text{Average volume loss of experimental pads}} \times 100$$

Compound formulations are given in Table 1.

RESULTS AND DISCUSSION:

Brass-plated wire cloth (National-Standard Company, 16x14 mesh, .013 Hi-Carbon C-1055 brass-plated warp wire x .020 Low Carbon C-1008 steel wire with no coating fill wire), when laminated with rubber in alternate horizontal layers (seven layers of rubber and six layers of wire cloth) was previously found[10] to provide outstanding improvement in resistance to heat buildup of experimental track pad compounds in laboratory tests with the Firestone Flexometer. Experimental track pads containing the wire cloth reinforcement, however, displayed poor wear resistance in service tests.[10] Examination of the wire reinforced pads upon completion of test revealed that the wire cloth actually had an adverse affect on wear resistance. Delamination of the pads in the area of the wire cloth resulted in excessive chunking and tearing and premature loss of rubber, as shown in Figure 1. Tests were run using the Firestone Flexometer to determine if lesser amounts (three layers) of wire cloth positioned horizontally at different points within the specimen or the same amount (six layers) of wire cloth positioned vertically within the specimen would display the outstanding resistance to heat buildup exhibited by specimens containing six layers of wire cloth positioned evenly throughout. Firestone Flexometer specimens were prepared, as shown in Figure 2, by lamination of the wire cloth with the uncured rubber and then compression molding the specimens in the usual manner. Each piece of wire cloth measured 1/2 inch by 1 1/2 inches and weighed approximately one gram. When six pieces of wire cloth were used in the preparation of the specimens, the total wire cloth content amounted to approximately 20 parts/100 rhc, by weight, of rubber. The resistance-to-heat buildup was determined by use of the Firestone

10 Bergstrom, *Ibid*

Flexometer. The time required for the temperature to rise from 100^{o}F to 200^{o}F was measured when the specimens were subjected to test conditions of 0.25-inch throw and 600-pound loading. Test results are given in Table 2 in which the Research Directorate SBR 1500 control compound (S152-1) was used as the base. The use of only three layers of wire cloth positioned horizontally in various areas within the specimens was not as effective as six layers in the improvement of the resistance-to-heat buildup. Although the specimens containing three layers of wire cloth exhibited no tearing or delamination in this test, the time for the temperature to rise from 100^{o}F to 200^{o}F was much shorter for these specimens than for the specimens containing six layers of wire cloth positioned horizontally (23 or 28 minutes vs. 104 minutes). If the specimens containing the three layers of wire cloth had been flexed as long as 104 minutes, the dynamic action of the wire cloth on the rubber may have induced some tearing of the rubber, regardless of deterioration due to heat buildup. The specimens containing six layers of wire cloth positioned vertically had much poorer resistance-to-heat buildup than the control specimens and exhibited significant tearing of the rubber around the wire cloth. Even though resistance-to-heat buildup may be improved in some cases, the use of wire cloth in track pads is not feasible because of the chunking and delamination problem associated with its use under dynamic conditions. The problem may be similar to that observed in steel-belted radial tires operated at high speeds. In the 7 April 1975 issue of Rubber & Plastics News, the Department of Transportation gave warning that steel-belted radials may disintegrate at high speeds due to tread and belt separation. Similarly, on 14 March 1975, the U.S. Law Enforcement Assistance Administration (LEAA) of the Department of Justice issued a warning that steel-belted radial tires can break down and disintegrate at high speeds.

Numerous potential chemical heat stabilizers were evaluated in the Research Directorate SBR 1500 control compound (S152-1) and in proven wear-resistant experimental track pad compounds based on Stereon 750 (stereo-specific SBR) (S227-2), Philprene 1609/Cis-4 1350 (SBR/polybutadiene blend) (S212-2), and HYTRANS 1227-289-1 (alfin catalyzed copolymer of butadiene/styrene) (S223-4) to determine their effect on the resistance to heat buildup. The evaluation of these heat stabilizers also included the determination of their effect on (1) stress-strain properties at ambient temperature, 300^{o}F and after aging 70 hours at 212^{o}F, and (2) tear, Die C, at ambient and 250^{o}F. These results are given in Tables 3-6 and are summarized below:

1. Heat Stabilizers Which Provided Significant Reduction in Heat Buildup (Firestone Flexometer)

Compound Type and Number	Heat Stabilizer
a. Research Directorate SBR 1500 control compound (S152-1)	Dythal (dibasic lead phthalate) Cadmium oxide A189 (silane coupling agent)

Compound Type and Number	Heat Stabilizer
b. Stereon 750 (S227-2)	Dythal Cadmium oxide
c. Philprene 1609/Cis-4 1350 (S212-2)	Dythal Cadmium oxide
d. HYTRANS 1227-289-1 (S223-4)	Dythal Cadmium oxide Manganese Dioxide

2. Heat Stabilizers Which Provided Significant Improvement in Retention of Tear Strength When Measured at 250°F

Compound Type and Number	Heat Stabilizer
a. Research Directorate SBR 1500 control compound (S152-1)	Dyphos (dibasic lead phosphite) A189 Manganese dioxide Rio Resin
b. Stereon 750 (S227-2)	None
c. Philprene 1609/Cis-4 1350 (S212-2)	Dyphos A189
d. HYTRANS 1227-289-1 (S223-4)	None

3. None of the heat stabilizers significantly improved the retention of physical properties measured at 300°F or after aging 70 hours at 212°F.

SBR 1500 vulcanizates reinforced with silica (Hi Sil 233)/ carbon black and silica/ground quartz (Neo Novacite)/carbon black in conjunction with a silane coupling agent (A189) were also evaluated for resistance to heat build-up and heat resistance in general. Silica-reinforced SBR tire tread stocks were reported[11] to have superior resistance to cutting, chipping, and tear over carbon black reinforced stocks, and silica/ground quartz reinforcement provided[12]

11 Letter report from PPG Industries, Inc., date 6 June 1972.
12 Bergstrom, E.W., "Additives for Improving Heat Stability of Silicone Vulcanizates," Rock Island Arsenal Laboratory Technical Report 61-3505, 26 September 1961.

excellent heat resistance to silicone vulcanizates. The results of this evaluation are given in Table 7 in comparison with the Research Directorate control compound (S152-1), and show the following:

1. The Hi Sil 233/Neo Novacite/Statex 160 reinforced vulcanizates containing the A189 silane coupling agent (S152-170 and S152-171) exhibited significantly improved resistance-to-heat buildup over that of the S152-1 control compound, but had poorer tear resistance at ambient temperature and at 250°F.

2. The Hi Sil 233/Statex 160 reinforced vulcanizates, with or without the A189 silane coupling agent (S152-166, S152-167 and S152-168), had somewhat better tear resistance at ambient temperature than the S152-1 control compound, but had poorer or equivalent resistance to heat buildup.

3. The effectiveness of the A189 silane coupling agent is evident in all cases in which it was used, as shown by an increase in ambient tensile strength and moduli, and a decrease in ultimate elongation as the quantity of A189 was increased from zero to 1.0 part/100 rhc.

4. The physical properties of the Hi Sil 233/Statex 160 reinforced vulcanizates (with or without A189) and the Hi Sil 233/Neo Novacite/Statex 160 reinforced vulcanizates (with or without A189) measured at ambient temperature and at 300°F, and after 70 hours of aging at 212°F are in general poorer than those of the S152-1 control compound. The properties of S152-168 come close to equaling those of the control.

Because of the oil shortage, the availability of synthetic rubbers (especially those based on styrene, butadiene, and chloroprene) began to decrease significantly during the winter months of 1973-1974. The December 1973 issue of Rubber Age carried the statement that the ready availability of natural rubber (pale crepe and smoked sheet) might tend to diminish the problem of synthetic rubber shortages. For this reason, Rodman Laboratory began to evaluate the properties of vulcanizates prepared from blends of natural rubber with elastomers that had provided pads with significant resistance to tread wear in various service tests. Stereon 750, alfin catalyzed copolymers of butadiene/styrene and butadiene/isoprene (HYTRANS rubbers), and an SBR/Cis-4 polybutadiene blend were included. The effect of blending natural rubber with SBR 1500 in the Research Directorate control formulation (S152-1) was also studied. The results are given in Tables 8-12 and exhibit the following findings:

1. <u>SBR 1500/Pale Crepe Blends</u>

a. The resistance to tear at both ambient and elevated temperatures, and the resistance to abrasion and crack growth improved dramatically when the ratio of SBR 1500/pale crepe changed from 60/40 to 40/60.

b. Stress-strain properties measured at ambient temperature were not affected as increasing amounts of pale crepe were blended with the SBR 1500. However, the retention of properties measured at 300°F and 400°F improved significantly (on the basis of tensile and elongation retention at 300°F, and retention of elongation at 400°F) as the ratio of SBR 1500/pale crepe changed from 60/40 to 40/60.

c. The flexibility, as measured by ASTM D1043, was better at lower temperatures for the SBR 1500/pale crepe blended vulcanizates than for the vulcanizate prepared from SBR 1500 alone.

2. Stereon 750/Pale Crepe Blends

a. Resistance to tear at both ambient and elevated temperatures improved linearly as increasing amounts of pale crepe were used in Stereon 750/pale crepe blends.

b. Abrasion resistance was adversely affected, but resistance to crack growth was significantly improved when the ratio of Stereon 750/pale crepe changed from 82.5/40 to 55/60.

c. A significant increase occurred in moduli measured at ambient and elevated temperatures as the amount of pale crepe in the Stereon 750/pale crepe blends increased.

d. The low temperature stiffness was poorer for the blended vulcanizates than for vulcanizates prepared from Steron 750 only.

3. HYTRANS (Butadiene/Styrene type)/Pale Crepe Blends

a. Resistance to tear at ambient temperature improved significantly as the HYTRANS/pale crepe ratio changed from 82.5/40 to 55/60. Except for the 27.5/80 HYTRANS/pale crepe blend, resistance to tear at elevated temperatures for the other blends was not significantly different from that of the vulcanizate prepared from HYTRANS only.

b. Resistance to abrasion was significantly better for the blended vulcanizates than for the vulcanizate prepared from HYTRANS only, but no improvement in resistance to crack growth was noted until the pale crepe portion of the blend was increased from 60 to 80 parts.

c. The moduli measured at ambient and elevated temperatures were significantly higher for the blended vulcanizates than for those of the vulcanizate prepared from HYTRANS only.

d. Resistance to low temperature stiffness was somewhat better for the blended vulcanizates than for the vulcanizate prepared from HYTRANS alone when T_{200} values were measured by ASTM D1043.

4. HYTRANS (Butadiene/Isoprene Type)/Pale Crepe Blends

a. Resistance to tear at ambient and elevated temperatures improved linearly as increasing amounts of pale crepe were used in the HYTRANS/pale crepe blends.

b. Resistance to abrasion and crack growth, and resistance to stiffness at low temperature were adversely affected when pale crepe was blended with HYTRANS.

c. Moduli, especially those measured at ambient temperature and at 300°F, increased significantly as increasing amounts of pale crepe were used in the HYTRANS/pale crepe blends.

5. Philprene 1609/Cis-4 1350/Pale Crepe Blends

(As noted in Table 12, supplemental amounts of carbon black, Statex 160, were added to the pale crepe blended vulcanizates as the amount of the master batch carbon black contained in the Philprene 1609 and Cis-4 1350 decreased.)

a. Tear resistance at ambient temperature and resistance to crack growth improved dramatically when the ratio of Philprene 1609/Cis-4 1350/pale crepe changed from 60.9/38.7/40 to 40.6/25.8/60. Tear resistance measured at elevated temperatures increased linearly as the amount of pale crepe in the blends increased.

b. The abrasion resistance was somewhat better for the pale crepe blended vulcanizates than for the vulcanizate prepared from a blend of only Philprene 1609 and Cis-4 1350.

c. Resistance to low temperature stiffness was not significantly affected by the addition of pale crepe. When pale crepe was blended with SBR 1500, Stereon 750, HYTRANS (Butadiene/Styrene Type), and HYTRANS (Buradiene/Isoprene Type), the ozone resistance was adversely affected, as is shown in Tables 8,9,10, and 11. This can be remedied by use of increased amounts of antiozonant.

Because of the success achieved in the improvement of certain properties of SBR 1500, Stereon 750, HYTRANS or SBR/polybutadiene when these elastomers were blended with natural rubber (pale crepe), a study was made to determine the effect of the blending of these same elastomers with a synthetic natural rubber, Ameripol SN 600. Since the most dramatic improvement in most properties occurred in elastomer ratios containing 60 parts of pale crepe, these same blend ratios were chosen for evaluation with the Ameripol SN 600. The results given in Table 13 show that in general the effect on physical properties of the blending of Ameripol SN 600 with the various elastomers was the same as the effect of the pale crepe when blended with the same elastomers (Tables 8-12). Thus, either natural rubber (pale crepe) or synthetic natural rubber (Ameripol SN 600) could be used interchangeably to significantly improve resistance to tear or abrasion.

Because EPDM vulcanizates are inherently ozone resistant and have excellent age resistance, even at temperatures as high as 250°F, these vulcanizates were considered as choices for use in track pads. However, the EPDM vulcanizates were only as abrasion resistant as the SBR vulcanizates, and experimental track pads prepared from EPDM exhibited no improvement in wear resistance over SBR in service tests. Numerous means of improving the abrasion resistance of a fast-curing EPDM (EP syn 55) were evaluated without success during FY 1973.[10] Because of the significant improvement in abrasion resistance imparted to SBR 1500, HYTRANS (butadiene/styrene type), and SBR/polybutadiene when blended with pale crepe, blends of EPDM/pale crepe were evaluated. These results are given in Table 14 and show that a 40/60 EP syn 55/pale crepe blend (E59-14) has significantly improved abrasion resistance when compared to the EP syn 55 control compound (E59). The addition of pale crepe to EP syn 55 also improved resistance to crack growth (DeMattia tester) and low temperature flexibility (ASTM D1043). Tear resistance, especially at ambient temperature, was not improved. The addition of Dyphos and Rio Resin to the 40/60 EP syn 55/pale crepe blended vulcanizate did not improve tear resistance. The use of these additives, known to improve the tear resistance of SBR 1500 and SBR/polybutadiene vulcanizates, also had an adverse affect on abrasion resistance. Because of the significant improvement in resistance to abrasion and crack growth afforded EPDM when blended with pale crepe, further attempts to improve the tear resistance of this blend would be worthwhile.

In an article[13] appearing in the May 1973 issue of Rubber Age, the introduction to the rubber market of a new high Mooney flame retardant SBR was described by the B.F. Goodrich Chemical Company. The results of the evaluation of this new elastomer, Ameripol 4713, are given in Table 15 in comparison with the Research Directorate control compound (S152-1). The vulcanizate prepared from Ameripol 4713 (S252) exhibited significantly improved resistance to both abrasion and tear at elevated temperatures when compared with compound S152-1, but exhibited poorer resistance to crack growth. Because of the poor resistance to crack growth, the conclusion was

10 Bergstrom, Ibid

13 Shah, A.K., Hallman, R.W. and Sarbach, D.V., "Flame Retardant SBR," Rubber Age, Vol. 105, No. 5, May 1973, pp. 37-42.

that this compound would be unsuitable for rubber track pads. This Laboratory has since learned that Goodrich has withdrawn this elastomer from the market.

At the request of the U.S. Army Tank-Automotive Command (TACOM), Warren, Michigan, work was done on blends of Stereon 750 and HYTRANS (both SBR and butadiene/isoprene types) with a fast-curing EPDM (EP syn 55) and brominated butyl (Polysar Bromobutyl X2). The effect on the blends of an SAF vs. an FEF black, and blends of the two blacks was also studied. These results are given in Tables 16-18. Since the Stereon 750 and HYTRANS elastomers contain 37.5 parts oil, appropriate amounts of the same type of oil were added to the blends so that the parts oil/100 rhc in all compounds would remain the same. Generally, from the results, the conclusion follows that neither the use of blends nor the use of FEF black or FEF/SAF black in place of all SAF black provided significant improvement to the originally developed base compounds (S227-2, S223-4 and B33-4) in the combination of properties essential to provide improved wear-resistant compounds, namely, resistance to abrasion, tear, and crack growth. In no case were all three essential properties improved. Resistance to crack growth was generally better for those compounds in which FEF black only was used, but the tear and abrasion resistance of these compounds was much poorer than the originally developed base compound prepared from Stereon 750 or HYTRANS only, and in which only SAF black was used. Resistance to tear at ambient and elevated temperatures, and abrasion resistance of all the experimental compounds was equivalent or, in most cases, much poorer than that found for the base compounds. Original tensile strengths were also poorer for all the experimental compounds than for the base compounds. None of the experimental compounds were considered suitable choices for track pad evaluation.

During FY1975, a new class of reinforcing fibers was introduced to the market by Monsanto Industrial Chemicals Company.[14] These reinforcing agents are unregenerated cellulose fibers coated with a proprietary polymeric agent for better bonding of the fiber to the rubber and have the trade name "Santoweb". Three grades of the Santoweb fibers are marketed. They are Santoweb D for highly unsaturated polymers such as SBR, natural rubber, polyisoprene, polybutadiene and neoprene; Santoweb H for EPDM, butyl, and other low unsaturated polymers; and Santoweb K for such highly polar polymers as nitriles and urethanes. Santoweb D was evaluated at 5 and 15 parts/100 rhc in compounds based on SBR 1500 (Research Directorate control compound) (S152-1), an SBR 1500/pale crepe blend (A50-3), Stereon 750 (S227-2), Philprene 1609/Cis-4 1351 (S212-2), HYTRANS (SBR type) (S223-4), and HYTRANS (butadiene/isoprene type) (B33-4). Resimene 3520, a modifier recommended by Monsanto for use in conjunction with the Santoweb fibers to enhance rubber-to-fiber bonding, was used at a concentration of 1 part/100 rhc. The results, given in Tables 19-24, show the following:

14 Boustany, K., and Hamed, P., "The Effect of Santoweb Fibers on the Tensile Modulus Properties of Natural and Synthetic Rubber." Paper presented at a meeting of the Philadelphia Rubber Group, September 1974.

1. SBR 1500 (Research Directorate Control Compound)

a. The addition of Santoweb D had an adverse effect on abrasion resistance, resistance to crack growth, ozone resistance, and ambient tensile strength.

b. Tear resistance at ambient temperature was significantly improved by the addition of Santoweb D, but tear resistance at 250°F was not significantly affected.

2. SBR 1500/Pale Crepe Blend

a. Resistance to abrasion, crack growth, and ozone were adversely affected by the addition of Santoweb D. Ambient tensile strength was adversely affected only when 15 parts/100 rhc Santoweb D were employed.

b. Tear resistance at ambient temperature was significantly improved by the addition of Santoweb D, but resistance to tear at 250°F was not significantly affected.

3. Stereon 750

a. The addition of Santoweb D had an adverse effect on resistance to crack growth and ozone. Ambient tensile strength was adversely affected only when Santoweb D was used at the 15-part level.

b. Resistance to tear at ambient was significantly improved by the addition of Santoweb D, but tear resistance at 250°F was not significantly affected.

c. Abrasion resistance was significantly improved by the additon of Santoweb D, particularly at the 5-part level.

4. Philprene 1609/Cis-4 1351 Blend

a. Resistance to abrasion and crack growth and tensile strength at ambient were adversely affected by the addition of Santoweb D.

b. Tear resistance at both ambient and elevated temperatures was significantly improved by the addition of Santoweb D.

5. HYTRANS (SBR type)

a. The addition of Santoweb D had an adverse effect on abrasion resistance, ambient tensile strength, and ozone resistance. Resistance to crack growth was adversely affected only when Santoweb D was used at the 15-part level.

b. Tear resistance at ambient was slightly improved by the addition of Santoweb D, but tear resistance at 250°F was adversely affected.

6. HYTRANS (Butadiene/Isoprene Type)

a. Resistance to abrasion, crack growth and ozone, as well as tensile strength at ambient, were adversely affected by the addition of Santoweb D.

b. Tear resistance at ambient was somewhat improved by the addition of Santoweb D, but tear resistance at 250°F was slightly poorer for the compounds containing Santoweb D.

Because of the adverse effect of Santoweb D on the resistance to abrasion and/or crack growth, none of the compounds in which Santoweb D was used (Tables 19-24) are considered suitable choices for track pad service testing.

Arrangements were made through TACOM to test Research Directorate experimental T142 track pads in a service test performed at Yuma Proving Ground, Yuma, Arizona, during June through September 1975. Experimental pads selected and prepared for this test were based on the following compounds:

1. Research Directorate SBR 1500 control compound (S152-1).
2. SBR 1500/Pale Crepe Blend (A50-3).
3. Stereon 750 (S227-2).
4. Stereon 750/Pale Crepe Blend (A51).
5. HYTRANS 1697-259-1 (SBR Type) (S223-4).
6. HYTRANS 1697-259-1/Pale Crepe Blend (A52).
7. Philprene 1609/Cis-4 1351 Blend (S212-2).
8. Philprene 1609/Cis-4 1351/Pale Crepe Blend (A54).
9. Stereon 750 (Reinforced with carbon and mineral fillers and containing a silane coupling agent) (S227-21).
10. SBR 1500 (Contains Dyphos for improving retention of tear strength at 250°F) (S152-160).
11. Philprene 1609/Cis-4 1351 Blend (Contains Dyphos for improving retention of tear strength at 250°F (S212-7).

Physical properties determined on the Banbury mixed batches of these compounds are given in Table 25.

In addition to the T142 pads prepared from the compounds listed above, experimental pads having a more rounded contour than the conventional T142 pad (Figure 3) were also prepared for service testing. In previous service tests, the initiation of cracking and chipping was attributed to the sharp edges of the conventional T142 pads, and the theory was that "rounding off" these edges might reduce the shearing action on the edges and, thereby, result in pads having improved wear resistance. Pads having the rounded contour were prepared from SBR 1500 (Research Directorate Control Compound) (S152-1) and Stereon 750 (S227-2) by grinding off the corners of conventional T142 pads using a rubber grinding wheel. The rounded pads were then coated with one coat of a conventional tire dressing to duplicate the mold skin of the conventional pads.

Results of the service test at Yuma are given in Table 26. Tests were conducted for 500 miles on paved track using an M60A1 vehicle having a total weight of 107,000 pounds. These results show the following:

1. With the exception of Compound S227-21, experimental pads based on Stereon 750, HYTRANS (SBR Type), and Philprene 1609/Cis-4 1351 exhibited significantly improved wear resistance when compared with the commercial controls.

2. The addition of pale crepe to Stereon 750 and Philprene 1609/Cis-4 1351 significantly improved the wear resistance of pads based on these elastomers. The addition of pale crepe did not significantly affect the wear resistance of pads based on SBR 1500 or HYTRANS (SBR Type); however, significant improvement may have become evident if the pads had been run on gravel and cross-country courses.

3. The rounded contour pads based on SBR 1500 and Stereon 750 did not exhibit significantly improved wear resistance over that of the conventionally styled pad.

4. The addition of Dyphos did not improve the wear resistance of pads based on SBR 1500 or Philprene 1609/Cis-4 1351, and pads based on carbon black-mineral filled Stereon 750 exhibited very poor wear resistance.

All research efforts on the development of rubber compounds for use in tank track pads have been concluded by the Research Directorate at this Arsenal. A summary of all work accomplished by this Laboratory on the problem over the past thirteen years is given in the appendix.

CONCLUSIONS:

Although resistance to heat buildup through the use of wire cloth may be improved in some cases, the use of wire cloth in track pads is not feasible because of the chunking and delamination that occur under dynamic conditions.

Certain heat stabilizers provided a significant reduction in heat buildup to various vulcanizates while others provided a significant improvement in tear resistance at 250°F. Dythal (dibasic lead phthalate) and cadmium oxide provided a significant reduction in heat buildup to SBR 1500, Stereon

750, HYTRANS (SBR Type), and a Philprene 1609/Cis-4 1350 blend. Dyphos (dibasic lead phosphite) and A189 (a silane coupling agent) provided a significant improvement in tear resistance at 250°F to SBR 1500 and a Philprene 1609/Cis-4 1350 blend. None of the heat stabilizers significantly improved the retention of physical properties measured at 300°F or after aging 70 hours at 212°F.

Blending of pale crepe with SBR 1500, Stereon 750, HYTRANS or SBR/polybutadiene improved the resistance to abrasion, tear, and crack growth in most cases. Significant improvement was generally noted when the pale crepe portion of the blend was 60 parts. The effect on various physical properties when a synthetic natural rubber (Ameripol SN600) was blended with SBR 1500, Stereon 750, HYTRANS or SBR/polybutadiene was the same as that found when natural rubber (pale crepe) was blended with the same elastomers. Therefore, either natural rubber (pale crepe) or synthetic natural rubber (Ameripol SN 600) can be used interchangeably in those formulations to improve tear, abrasion or crack growth.

In an attempt to improve the abrasion resistance of a fast curing EPDM, various EPDM/pale crepe blends were evaluated. A 40/60 EPDM/pale crepe blend was found to have significantly improved resistance to abrasion and crack growth when compared to a vulcanizate prepared from EPDM only; but the tear resistance of the blend was adversely affected.

The effect of blending Stereon 750 or HYTRANS elastomers with a fast-curing EPDM and brominated butyl was investigated. The effect of an SAF vs. an FEF black, and blends of the two blacks on the blended vulcanizates was also studied. Neither the use of various elastomeric blends nor the use of FEF black or FEF/SAF black in place of all SAF black was found to provide any significant improvement in the originally developed Stereon 750 and HYTRANS base compounds as far as resistance to abrasion, tear, and crack growth was concerned.

Santoweb D fibers, unregenerated cellulose fibers coated with a proprietary polymeric agent for better bonding of the fibers to rubber, were evaluated in SBR 1500, SBR 1500/Pale Crepe, Stereon 750, HYTRANS and SBR/polybutadiene vulcanizates. The Santoweb D fibers had an adverse effect on the resistance to crack growth of all the vulcanizates.

Several experimental compounds, particularly those based on blends of the most wear-resistant elastomers found previously with pale crepe, were considered suitable choices for providing rubber track pads with improved wear resistance. Experimental T142 pads were prepared from these compounds and were service-tested at Yuma Proving Ground. Experimental T142 pads, having a more rounded contour than the conventional T142 pads, were also prepared for service testing at Yuma. Pads based on Stereon 750, HYTRANS (SBR Type), and Philprene 1609/Cis-4 1351 exhibited significantly improved wear resistance when compared with commercial controls. The addition of pale crepe to Stereon 750 and Philprene 1609/Cis-4 1351 significantly improved the wear resistance of pads based on these elastomers. The rounded contour pad did not exhibit significantly improved wear resistance over that of the conventionally styled pad.

This Laboratory believes that the combination of shearing force and ground pressure placed on the rubber track pads, because of the weight of the M60-series tank (100,000 pounds or more), may exceed the capabilities of currently available elastomers to significantly resist such forces under dynamic (vehicle-moving) conditions. Possibly, because of the vehicle weight factor, a 5000-mile T142 rubber track pad may never be a reality, no matter how designed, but a T142 pad having a life of 3500 miles can now be obtained with compounds based on those elastomers described herein.

RECOMMENDATIONS:

Scale-up to production levels (in pilot lot quantities) should be continued by TACOM on all experimental compositions which exhibit significant improvement in wear resistance in service tests.

Any new low-cost general purpose elastomer introduced commercially that might be expected to produce more wear-resistant track pads should be evaluated to advance the state of the art of track pad technology.

ACKNOWLEDGEMENT:

The assistance of Mr. James Ruby of the Research Directorate in the Banbury mixing of the numerous experimental compounds required for track pad preparation is very much appreciated.

The cooperation of Mr. C. Dale Maas, SARRI-PF, Rock Island Arsenal, in granting permission to use this Arsenal's rubber production facilities is also appreciated. The availability of the shop size Banbury mixer and roll mills greatly reduced the time and effort required to mix the large batches of rubber needed in the preparation of the experimental track pads.

Note: The larger the volume wear rating figure, the better the wear resistance

APPENDIX

Summary of Work performed by the Research Directorate, General Thomas J. Rodman Laboratory, Rock Island Arsenal, to Improve the Wear Resistance of Rubber Tank Track Pads.

Time Period Covered: FY63 thru FY75, continuously.

Research Directorate Personnel Involved in R&D Effort:

- R.F. Shaw (deceased)
- Z.T. Ossefort (deceased)
- R.E. Ofner
- J.W. McGarvey
- W.M. Veroeven
- J.R. Cerny
- E.W. Bergstrom

Funding Agencies:

U.S. Army Materials and Mechanics Research Center
Watertown, MA

U.S. Army Tank-Automotive Command
Warren, MI

Number of Experimental Compounds Prepared and Evaluated - 950

Type of Elastomers or Elastomeric Blends Evaluated (by Trade Name):

Genthane S
Genthane S/EPR 404
Genthane SR

Stereon 750/Pale Crepe
HYTRANS (SBR)/Pale Crepe
Philprene 1609/Cis-4 1351/Pale Crepe
Polycarbonate
Injection molded glass reinforced ESTANE urethanes
SBR 1500 (contains rubber impregnated chopped strand-RICS)
HYTRANS (Butadiene/Isoprene Type) (contains RICS)
Philprene 1609/Cis-4 1350 (contains RICS)

Types of Compounds Which Exhibited Significant Improvement in Wear Resistance:

Compound Description	Wear Rating (Durability) Range (Based on 3 or more tests)	Comments
Genthane S	76-123	Elastomer proved to be hydrolytically unstable; moderately expensive; withdrawn from market.
Genthane SR	79-150	Elastomer proved to be hydrolytically unstable; porosity developed in pads run at high speeds; moderately expensive; withdrawn from market.
Stereon 750	110-216	Has advanced to pilot lot test stage.
Philprene 1609/Cis-4 1350 (or Cis-4 1351)	145-196	Has advanced to pilot lot test stage
Ameripol 1634/Ameripol CB 1352	141-171	Did not reach pilot lot test stage because of difficulties encountered by TACOM in obtaining elastomers from B.F.Goodrich.
HYTRANS (SBR Type)	124-179	Has not reached pilot lot test state; commercial availability in doubt.
HYTRANS (Butadiene/ Isoprene Type)	126-154	Has not reached pilot lot test stage; commercial availability in doubt

Significant Findings in Efforts to Improve Wear Resistance

1. Significant improvement in wear resistance has been achieved from compounds based on certain low cost, general-purpose type elastomers, namely Stereon 750, HYTRANS copolymers of butadiene/styrene or butadiene/isoprene and SBR/polybutadiene blends.

2. Numerous reinforcing agents, other than or in addition to carbon black, were evaluated in various elastomers. These included cotton flock, Nylon flock, Dacron flock, Fiberglas rubber impregnated chopped one inch strand

(RICS) (Owens-Corning), 100:100 lignin: rubber latex coprecipitates (National Research Council of Canada), Duoform 3/4 inch fiber wire (National Standards Co.), brass-plated and low-carbon electro galvanized wire cloth (National Standard Co.) and Santoweb D, an unregenerated cellulose fiber (Monsanto Chemical Co.). None of the reinforcing agents were effective in providing compounds with significant improvement in wear resistance.

3. A 50/50 combination of U.O.P. 88/Santoflex AW significantly improves the resistance to crack growth of vulcanizates based on SBR 1500, Stereon 750, HYTRANS copolymers and an SBR/polybutadiene blend.

4. The blending of natural (pale crepe) or synthetic natural (Ameripol SN 600) rubber with SBR 1500, Stereon 750, HYTRANS copolymers or an SBR/polybutadiene blend significantly improves the resistance to tear, abrasion and crack growth of the resulting vulcanizates.

5. Examination of 17 years of service test data revealed that the main causes of track pad failure were chunking, cutting, abrasion and bond failure. Blowouts (heat buildup) and delamination were infrequent causes of failure. Internal pad temperatures generally averaged 250°F during operation, but temperatures in excess of 350°F have been recorded on occasion.

6. Correlation was found to exist between service test data and laboratory test data for tear, abrasion and crack growth when all three laboratory tests are considered together. In those instances where the laboratory values for tear, abrasion and crack growth are <u>all</u> better than the corresponding values found for the Research Directorate SBR 1500 control compound (S152-1), the service test wear rating is better than that of the Research Directorate control compound which has given wear ratings almost identical to those of commercial SBR pads in numerous service tests. If only one or two of the three properties is inferior to those of the Research Directorate control compound, the wear rating is lower.

7. An invertible rubber track pad was designed and developed by the Research Directorate for the T130 track. In practice the invertible concept provides for double service life by simply inverting the pad to expose a new surface after one surface has become worn. The invertible track pad concept was forwarded to TACOM for their consideration and possible adoption.

8. Injection molding of T130 pads proved feasible. Pads could be injection molded in 5-10 minutes at 350° or 400°F compared to a compression molding time of 75 minutes at 320°F. Physical properties of the injection-molded pads were found to be comparable to those of compression-molded pads. Pilot lots of injection-molded T130 pads have been obtained by

TACOM and are currently being tested. Early results indicate that the wear resistance of the injection-molded pads is significantly better than that of compression-molded pads prepared from the same compounds.

9. Excellent rubber-to-metal vulcanization bonding systems have been found for all the experimental compounds which have exhibited significantly improved wear resistance in service tests.

WEAR-RESISTANT-RUBBER TANK TRACK PADS, by Edward W. Bergstrom

Report R-TR-76-028, October 1975, 67 p., incl. illus. tables, (PRON A1-5-R0005-01-AW-M5, AMC Code 612105. 11.H8400) Unclassfied report.

Certain chemical heat stabilizers provided a significant reduction in heat buildup to various experimental track pad vulcanizates while others provided a significant improvement in tear resistance at 250°F. Although the resistance to heat buildup through the use of wire cloth may be improved in some cases the use of wire cloth in track pads is not feasible because of the chunking and delamination problems associated with its use under dynamic conditions. Blending natural or synthetic natural rubber with SBR 1500, Stereon 750, HYTRANS or SBR/polybutadiene
