SUBJECT TO EXPORT CONTROL LAWS

CFIA

This document contains information for manufacturing or using munitions of war. Exporting this information or releasing it to foreign nationals living in the United States without first obtaining an export license violates the International Traffic in Arms Regulations. Under 22 USC 2778, such a violation is punishable by up to 2 years in prison and by a fine of \$100,000.

Distribution limited to U.S. Government agencies only; Test and Evaluation, Dec 81. Other requests for this document must be referred to AFRPL/TSPR (Stop 24), Edwards AFB, CA 93523.

## NOTICE

Publication of this report does not constitute approval or disapproval of the ideas or findings. It is published in the interest of scientific and technical information exchange.

## FOREWORD

This report was submitted by the School of Aeronautics and Astronautics, Purdue University, West Lafayette, Indiana, 47907, under Contract F04611-78-C-0025, Job Order No. 2308MIDG with the Air Force Rocket Propulsion Laboratory, Edwards AFB, California 93523.

Volume I presents the results of a research program for determining the combustion response functions for a multimodal polydisperse composite propellant. Volume II is a User's Manual for the computer program, PEM, and is available on request. The co-principal investigators for the program were J. P. Renie and J. R. Osborn.

This technical report is approved for release and distribution in accordance with the distribution statement on the cover and on the DD Form 1473.

**Abstract:**

(U) Volume II is a user's manual for computer programs written to perform theoretical analyses described in Volume I. This volume describes the main routines and subroutines used in the analysis of the combustion of composite solid propellants both steady state and nonsteady state. Also, a detailed description of the input parameters required as well as the output generated is presented. Sample cases are provided to facilitate understanding of the programs so described. ## ABSTRACT

Volume II is a user's manual for computer programs written to perform theoretical analyses described in Volume I. This volume describes the main routines and subroutines used in the analysis of the combustion of composite solid propellants both steady and nonsteady state. Also, a detailed description of the input parameters required as well as the output generated is presented. Sample cases are provided to facilitate understanding of the programs so described.

## I. INTRODUCTION

A computer program has been developed for determining both the steady state and the nonsteady state response for a AP-based composite solid propellant. The theoretical combustion model is a multiple flame type model similar in many respects to the original Beckstead, Derr and Price (BDP) model. However, this model, the Petite Ensemble Model, or PEM, is unique in that it has the capability of representing the actual oxidizer particle size and size distribution of the propellant formulation within the burning rate calculational framework. The PEM has been modified to include a comprehensive aluminum particle model as well as an in depth erosive burning model. The aluminum model is based upon a mechanistic scenario of the aluminum particle behavior during the regression of the propellant surface, or burning. That is, the behavior of the aluminum particle is modeled from its emergence at the propellant surface, its flight away from the surface under the influence of viscous forces, its subsequent ignition and combustion within the hot gas stream above the surface, to its energy release due to combustion, some of which being transferred back to the propellant surface. It is this possibility of energy feedback to the propellant surface which allows the aluminum to affect the overall burning rate characteristics of the propellant under investigation. The erosive burning model is based on the concept that a turbulent boundary layer is formed above the burning propellant surface due to the presence of a crossflow velocity. It is due to this turbulent boundary layer that the gas phase transport properties are enhanced above their respective molecular values. This is the mechanism within the erosive burning PEM which accounts for increased burning rates, or erosive burning, in the presence of a crossflow of gas above the propellant surface.

In terms of nonsteady state combustion modeling, various pressure coupled and velocity coupled response models have been incorporated in the statistical PEM framework. The two primary nonsteady state response modeling efforts have been a small perturbation analysis and a Zeldovich/Novozhilov technique. In both cases, the nonsteady state behavior of the solid propellant is described in terms of steady state responses to various changes in combustion variable such as pressure, crossflow velocity, initial solid propellant temperature and surface temperature. Both the steady state and nonsteady state theoretical analyses upon which the computer program described herein is based is presented in the final report of this contract under separate cover.

This report presents a discussion of the computer program organization, a description of the various subroutines, a discussion of the input parameters, a brief interpretation of the output information and a number of sample cases to illustrate the various steady state and nonsteady state applications of the computer program.

## II. PROGRAM ORGANIZATION

### A. INTRODUCTION

In this section, the computer program overlay structure is presented along with a detailed discussion of the various calculational options afforded by the PEM computer program. Also, some general comments are made concerning the computer program input, parameter initialization and output.

### B. CALCULATIONAL OPTIONS

The framework upon which this computer program is based is a comprehensive version of the theoretical, multiple flame combustion model described earlier. This model, designated as the PEM, is a unique model in that the propellant's oxidizer particle size and size distribution can be specified. Using this model, steady state combustion parameters such as burning rate, pressure exponent, temperature sensitivity and erosive burning enhancement can be calculated. In such a manner, these parameters will depend on the actual oxidizer particle size and size distribution within the propellant formulation. Therefore, the basic core of the computer model is the calculation of the steady state burning rate of a propellant with a specified oxidizer distribution. If the propellant under consideration contains aluminum particles, these metal particles are subjected to a rigorous analysis. Such an analysis determines the behavior of the aluminum particles as they first emerge from the propellant surface, flow away from the surface due to viscous drag, and subsequently ignite and burn in the hot gas stream above the propellant surface. In the process of burning, heat is liberated some of which may be transferred back to the propellant surface thus contributing to the combustion mechanism of the surface regression.

If a crossflow velocity is assumed to be present above the burning propellant surface, then the erosive burning module of the computer program is entered and the nonerosive burning rate of the propellant is enhanced by an amount dependent on the transport property enhancement caused by the turbulent boundary layer above the propellant surface.

Having calculated the steady state burning rate of a propellant formulation in question, the computer program has the option to calculate both the pressure coupled or the velocity coupled response functions. Various nonsteady state response models can be used to calculate the desired nonsteady state response, the selection of the particular model being specified by the user. Finally, the nonsteady state response is calculated and presented as a function of the frequency of the nonsteady driving mechanism, be it pressure or velocity field oscillations.

As a final measure, the user has the option to specify whether or not the response function versus frequency data generated should be represented as a plotted curve. A detailed plotting routine has been incorporated into the PEM computer program. This plotting routine contains many of the standard CALCOMP calls and should be compatible on most systems. However, the user maintains the option to substitute his own plotting routines if so desired.

### C. PROGRAM OVERLAY STRUCTURE

The overall computer program consists of sixty-three routines (four program routines and fifty-nine subroutines). In order to minimize the amount of central memory required to load and run the computer program, a standard overlay scheme is employed. This overlay structure is presented in Figure 1. Two levels of overlaying are employed: the resident overlay level and the primary overlay level. OVERLAY (PEM0,0,0) is the resident overlay and it controls the overall execution of the computer program. In this overlay, all the steady state combustion modeling is performed except for the erosive burning calculational schemes. The steady state multiple flame modeling within this overlay contains the detailed aluminum modeling previously described. If a crossflow velocity above the propellant surface is present, then the first primary overlay, OVERLAY (PEM1,1,0) is called after the steady state non-erosive burning rate is calculated. Also, if nonsteady state pressure coupled or velocity coupled response calculations are desired, the second primary overlay, OVERLAY (PEM2,2,0), is called. It is within this overlay that the various nonsteady state response models are employed at the user's option in order to calculate the pressure coupled or velocity coupled response of the propellant formulation under consideration. Finally, after calling this overlay to perform the nonsteady state response calculations, the third and final primary overlay, OVERLAY (PEM3,3,0), can be called in order to plot the nonsteady state response results.

Figure 1. Program OVERLAY Structure

#### D. DATA INPUT

The input data for the computer program are entered through both namelist input and formatted read statements. The formatted read statements are only used in the plotting portion of the computer program. For the major modeling portion of the computer program, seven namelists must always be specified: namelists FLAG, PARMST, PROPDT, ALUMDT, EROSDT, RESPDT, and OXDIST. Namelist FLAG enters various control parameters for the steady state modeling portion of the program. Namelist PARMST contains parameters pertaining to the numerical analyses within the computer programming. Also, external environmental conditions such as the combustion pressure and the initial solid propellant temperature are specified through this namelist grouping. Namelist PROPDT contains parameters pertaining to the actual propellant formulation being considered. That is, the various oxidizer, fuel, and non-aluminum additives solid phase and gas phase properties are specified through this namelist. Namelist ALUMDT contains parameters related to the aluminum particle combustion modeling within the program. Various aluminum properties and program control parameters are specified through this namelist. Namelist EROSDT contains parameters related to the erosive burning modeling methodologies. The value of the crossflow velocity is entered through this namelist grouping. A non-zero value for this crossflow velocity directs the flow of the program into the erosive burning portion of the computer program. Namelist RESPDT contains parameters related to the nonsteady state modeling performed by the computer program. Control variables are entered into this namelist to direct the type of pressure coupled or velocity coupled response calculation to be performed. Finally, the last namelist, OXDIST, specifies the actual oxidizer particle size distribution of the propellant formulation being considered.

## E. OUTPUT

Each of the four program routines; LINK00, LINK10, LINK20, and LINK30, controls a portion of the overall output corresponding to the calculations performed within each of the program routines. The steady state calculations are outputted through the LINK00 routine, the erosive burning results are directed through the LINK20 routine, the nonsteady state response results are directed through the LINK20 routine and the output corresponding to the plotting results is directed through the LINK30 routine. However, some of the intermediate results are directed from many of the other subroutines within the program. The actual type of output provided will be discussed further when the many sample cases are presented. Primarily, the output consists of the input parameters, any intermediate calculational results, the final pseudo-propellant burning rates, both nonerosive and erosive, and the nonsteady state pressure coupled and velocity coupled response functions as functions of driving frequency.

## III. SUBROUTINE DESCRIPTIONS

### A. INTRODUCTION

In this section, a brief description is given of the function of each of the subroutines comprising the overall computer program. This information supplements the information available in the form of comment statements within the program listing available upon request from AFRPL. The many variables not detailed in the namelist input descriptions of Section IV will be described to aid in the discussion of the output presented for the many sample cases provided.

## B. OVERLAY (PEMO,0,0)

LINK00. This program routine is the main control routine in OVERLAY (PEMO,0,0), the resident overlay. From this routine, INPUT is called which directs the input of the seven namelist and provides the LINK00 routine with information as to what calculations are to be performed. Much of the program output is either generated from this routine or directed to the main output subroutine, OUTPUT. Also, the erosive burning routine, LINK10, the nonsteady state response routine, LINK20, and the plotting routine, LINK30, are called from this routine based upon the information provided through the namelist input groupings. At the end of this routine, the program has the capability of reading another case after storing any pertinent information in STORE or stopping altogether. As before, such control information is read in through the various namelist input groupings.

RCAL. This subroutine stores the pseudo-propellant burning rates during the course of the steady state calculations. Then, with the combustion model having calculated and stored the burning rate for each pseudo-propellant comprising the overall polydisperse propellant, this routine is again called and the overall propellant burning rate is calculated. This task is performed via an integration over all oxidizer particle sizes of the pseudo-propellant burning rates weighted by an oxidizer distribution function. IKING is a control variable within this subroutine causing the following results:

If IKING equals 0, a series summation technique is utilized to calculate the overall propellant burning rate from the pseudo-propellant information.

If IKING equals 1, a parallel summation technique is utilized to calculate the overall propellant burning rate from the pseudo-propellant information.

If IKING equals 2, a combination of the two schemes is performed; half series and half parallel summation.

If IKING equals 3, the user can specify the combination method employed. In the current version of the computer program, the percentage of each summation scheme is determined by a BETAR parameter, being calculated from the oxidizer distribution/pseudo-propellant burning rate data.

INPUT. This subroutine's primary function is to initialize and read the seven namelist input groupings; FLAG, PARMST, PROPD, ALUMD, EROSD, RESP, and OXDIST. In addition to reading these namelists, the two oxidizer integration diameter arrays, D(55) and XD(541), and their respective oxidizer distribution function arrays, FSKP(55) and XFSKP(541), are generated from the oxidizer particle size distribution data provided. The following parameters are also calculated based on the input propellant formulation data:

|           |                                                                                           |
|-----------|-------------------------------------------------------------------------------------------|
| XALFA     | the overall propellant oxidizer mass fraction.                                            |
| XNUT      | the overall propellant oxidizer volume fraction.                                          |
| RHOT      | the overall propellant density.                                                           |
| C         | the proportionality factor in the volume of fuel binder to volume of oxidizer (see CCAL). |
| ALFAV(55) | an array of pseudo-propellant oxidizer mass fractions.                                    |
| XNUV(55)  | an array of pseudo-propellant oxidizer volume fractions.                                  |
| RHOV(55)  | an array of pseudo-propellant densities.                                                  |

One should note that if the oxidizer diameter exponent,  $XN$ , equals three, each of the elements in the above three arrays are equal to  $XALFA$ ,  $XNUT$ , and  $RHOT$ , respectively, that is, the pseudo-propellant properties are equal to the overall propellant properties.

STORE. This subroutine is called initially from OUTPUT (INDEX=1) to store intermediate burning rate versus pressure theoretical and experimental data for a particular propellant formulation. It is called again from OUTPUT (INDEX=2) to store series and parallel summation theoretical burning rate information for each propellant. Finally, the subroutine is called a third time from LINK00 (INDEX=3) to direct the output of all the results for a series of propellants in order to investigate the theoretical versus experimental comparison for both burning rate and pressure exponent. Average percent errors are calculated and presented for each comparison. Once again, various series and parallel combinatory summation schemes can be employed via the IKING control parameter discussed above in RCAL.

OUTPUT. This subroutine outputs the many variables that are read into the computer program through the namelist input commands as well as the results of the steady state burning rate versus combustion pressure calculation for the propellant formulation under investigation. This subroutine stores the burning rate versus pressure data for NPRESS pressure values and then calls subroutine LSQFIT which performs a linear least square fit of the data. The results of such a calculation, the pressure exponent and a goodness of fit correlation coefficient, are then outputted.

DUMMY. This subroutine is a dummy subroutine used to load the binary read and write instructions. This procedure is required in order

for the computer program to run utilizing the FTN4 compiler version currently available at the Purdue University Computing Center (PUCC). This routine may not be necessary for other users at other computing facilities.

HAMRP. This subroutine directs the program flow for the nonsteady state pressure coupled response using the small perturbation method. The nonsteady state pressure coupled response is not calculated in this subroutine; this function is performed in the routine LINK20. However, the perturbation of the steady state model equations is performed whenever the control parameter, IRPHM, equals one. For each pseudo-propellant, the combustion pressure and surface temperature is perturbed systematically within the framework of the steady state burning rate calculations and the various  $f$  parameters, referred to in the theoretical analysis portion of the final report of this contract under separate cover, can be calculated and stored for future use in LINK20. From the values of the  $f$  parameters thus calculated, four parameter arrays,  $C(55,1)$ ,  $C(55,2)$ ,  $C(55,3)$  and  $C(55,4)$ , can be generated. Also, the zero frequency limit of the pressure coupled response function, the pressure exponent array,  $PXN(55)$ , can be filled.

DERRP. This subroutine directs the program flow for the nonsteady state pressure coupled response using either the method of Denison and Baum or the Zeldovich/Novozhilov method. The nonsteady state pressure coupled response is not calculated in this subroutine; this function is performed in the routine LINK20. However, the steady state  $d$  parameters, referred to in the theoretical analysis portion of the final report of this contract under separate cover, are calculated via a systematic perturbation of the combustion pressure and the initial solid propellant

temperature. The following steady state combustion parameter arrays thus calculated are as follows. The corresponding d parameter designation is also given where applicable.

- PXN(55) an array of pseudo-propellant pressure exponents ( $d_1$ ).
- PXM(55) an array of values related to the pseudo-propellant's sensitivity of surface temperature to changes in combustion pressure ( $d_3$ ).
- PXK(55) an array of values related to the pseudo-propellant's sensitivity of burning rate to changes in initial solid propellant temperature ( $d_2$ ).
- PXS(55) an array of pseudo-propellant temperature sensitivities.
- PXR(55) an array of values related to the pseudo-propellant's sensitivity of surface temperature to changes in the initial solid propellant temperature ( $d_4$ ).
- PXD(55) an array of pseudo-propellant properties ( $d_1 d_4 - d_2 d_3$ ).

Once these steady state combustion parameters are calculated, the following variables are also calculated for later use in the nonsteady state response calculations:

- AV(55) an array of pseudo-propellant Denison and Baum A parameters via the pressure perturbation scheme ( $d_1/d_3$ ).
- AVV(55) an array of pseudo-propellant Denison and Baum A parameters via the initial solid propellant temperature perturbation scheme ( $d_2/d_4$ ).
- BV(55) an array of pseudo-propellant Denison and Baum B parameters ( $1./d_2$ ).
- ES1(55) an array of pseudo-propellant effective surface activation energies via the pressure perturbation scheme.

ES2(55)        an array of pseudo-propellant effective surface  
                 activation energies via the initial solid propellant  
                 temperature perturbation scheme.

FLAMET. This subroutine computes flame temperatures and molecular weights of the flame combustion products based upon calculations previously performed with the NASA Thermochemistry Program. The adiabatic flame temperatures and molecular weights have been calculated at three separate values of combustion pressure; 34.0136, 68.0272 and 136.0544 atmospheres. Also, calculations have been performed for various oxidizer mass fractions from zero to one in increments of .05 for two types of fuel binder; HTPB (IFUEL=1) and PBAN (IFUEL=2). Therefore, by means of piecewise curve fitting of such data, the flame temperature and molecular weight can be calculated as a function of fuel type, oxidizer mass fraction and combustion pressure. The oxidizer is always considered to be ammonium perchlorate (AP). If the control parameter, ITFAD, equals one, then the curve fits are based on the temperature and molecular weight data inputted through the namelist PROPD. The adiabatic flame temperature and the molecular weight for the oxidizer monopropellant flame combustion products are also calculated as functions of pressure. Finally, the two flame temperatures are corrected for initial solid propellant temperature other than 294.15 K for which the data has been determined.

PEM. This subroutine controls the steady state burning rate calculation. This subroutine is called from any of the burning rate calculational control routines; LINK00, DERRP, HAMRP, EROSIV, HAMRV, or DERRV, returning with a value of burning rate, R. This value of burning rate is equal to the planar surface mass flux, MT, divided by the total propellant density, RHOT.

STEMP. This subroutine controls the surface temperature secant iteration scheme. E3, the difference between the assumed surface temperature and the calculated surface temperature based on the surface energy balance, is forced to converge to zero.

SOXCAL. This subroutine computes the burning surface geometry for a given oxidizer particle size pseudo-propellant. The propellant surface is assumed to be composed of equal numbers of positive and negative protruding or recessed oxidizer particles (positive and negative referring to the hemisphere of the oxidizer particle associated with the mean state). The fuel binder surface temperature, TSB, is iteratively computed if the separate surface temperature approach is assumed (ITS2=1) via satisfaction of continuity for both oxidizer and fuel mass flows. Surface roughness for the pseudo-propellant, RUFF(55), is calculated based on the observed surface geometry. Finally, a slipline correction factor, AFAC, is calculated if the equal mass fluxes assumption (ISLIP=1) is invoked by the user.

SEB. This subroutine solves the energy balance at the propellant surface. The major portion of this subroutine is used to control the calculation of the individual flame standoff distances. Also, the non-dimensional flame standoff distances and the flame heat release parameters are determined. With this information, based on an assumed value of surface temperature, the energy transmitted to the propellant surface from the various flames is computed and compared to the quantity of energy required to raise the propellant from its initial solid propellant temperature to the assumed surface temperature corrected for any exothermic or endothermic surface reactions. If equality is obtained, the proper

pseudo-propellant surface temperature is obtained. The following variables are calculated within this subroutine:

|       |                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------|
| XSTPF | the primary flame kinetic flame standoff distance.                                                            |
| XSTAP | the oxidizer monopropellant flame kinetic flame standoff distance.                                            |
| XSTPD | the primary flame diffusion flame standoff distance.                                                          |
| XSTFD | the final flame diffusion flame standoff distance.                                                            |
| QAP   | the oxidizer monopropellant flame heat release.                                                               |
| QPF   | the primary flame heat release.                                                                               |
| QFF   | the final flame heat release.                                                                                 |
| TSAP  | the percent contribution of the surface energy flux due to the oxidizer monopropellant flame.                 |
| TSPF  | the percent contribution of the surface energy flux due to the primary flame.                                 |
| TSFF  | the percent contribution of the surface energy flux due to the final flame.                                   |
| TSAL  | the percent contribution of the surface energy flux due to the combustion associated with aluminum particles. |

QALUM. This subroutine controls the portion of the steady state combustion model concerned with calculating the quantity of energy released during the combustion of aluminum particles that is transferred back to the propellant surface. This portion of the computer model is entered only if aluminum is present in the propellant formulation (BETA not equal to zero). The following six subroutines are concerned with the aluminum modeling mechanisms within the theoretical PEM.

SURFAL. This subroutine determines the state of the aluminum particle, that is, its temperature, TALS, as it emerges from the propellant

surface. The aluminum particle is assumed to heat up as it emerges from the surface. After emerging from the propellant, it flows away due to viscous drag forces again heating up due to its presence in the hot gas stream. If the temperature of the aluminum particle reaches the the aluminum oxide melting temperature, TSMELT, ignition occurs. The following variables are used during the aluminum combustion analysis and are described below for future reference, especially in discussing the sample case for an aluminized propellant.

|       |                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------|
| DAGGL | the diameter of the liquid aluminum particle.                                                                                       |
| VG    | the velocity of the hot gas stream issuing from the propellant surface.                                                             |
| TIGN  | time till ignition as referenced from the time of completed surface emergence of the aluminum particle.                             |
| XIGN  | distance above the propellant surface of the center of aluminum particle at the instant of ignition.                                |
| DLOFF | the diameter of the aluminum particle at lift off from the propellant surface.                                                      |
| VELP  | the velocity of the aluminum particle at the instant of ignition.                                                                   |
| TCOMB | the time for completed combustion of the aluminum particle.                                                                         |
| XCOMB | the distance above the propellant surface attained by the center of the aluminum particle at the moment of of completed combustion. |

EMERG. This subroutine performs the required incremental aluminum particle propellant surface emergence analysis. The primary function of

this subroutine is to calculate and keep track of the heat transfer to the aluminum particle from either the hot gas or the solid propellant during the emergence process. This information is necessary in order to establish the aluminum particle temperature/time relationship during this crucial point in the aluminum lifetime.

ALCOMB. This subroutine calculates the total heat transfer from the burning aluminum particle to the propellant surface as the aluminum particle accelerates away from the surface. A fourth order Runge-Kutta scheme is used in the integration of the heat release transferred to the propellant surface over the path traveled by the burning aluminum particle away from the propellant surface.

DVPDT. This subroutine calculates the instantaneous acceleration of the aluminum particle as a function of time and velocity.

CD. This subroutine calculates the coefficient of drag for a sphere as a function of the Reynolds number based on the aluminum particle diameter, the relative gas velocity and the gas phase properties.

ENHANC. This subroutine calculates the thermal conductivity enhancement factor at a specified distance above the propellant surface, YST. This value is calculated from the local value of eddy viscosity, EDY(461). If a crossflow velocity is not present and a turbulent boundary layer has not been calculated (IEDY=0) then a value of unity is returned.

TRANS. This subroutine is used to calculate the values of the transport properties of thermal conductivity and mass diffusivity as a function of flame zone average temperature, combustion pressure, and amount of boundary layer turbulence present. INDEX is a control parameter having the following effects:

If INDEX equals 0, the flame zone thermal conductivities are calculated.

If INDEX equals 1, the final flame zone diffusivity is calculated.

If INDEX equals 2, the primary flame zone diffusivity is calculated.

If INDEX equals 3, the boundary layer gas properties are calculated.

If INDEX equals 4, the gas stream properties are calculated for the aluminum modeling analysis.

The following parameters are calculated within this subroutine.

XLAMPF(55) an array of the pseudo-propellant primary flame zone thermal conductivities.

XLAMAP(55) an array of the pseudo-propellant oxidizer monopropellant flame zone thermal conductivities.

XLAMFF(55) an array of the pseudo-propellant final flame zone thermal conductivities.

GAMAPF(55) an array of the pseudo-propellant primary flame zone mass diffusivities.

GAMAFF(55) an array of the pseudo-propellant final flame zone mass diffusivities.

RESIST. This subroutine computes the average value of resistivity for an arbitrary distance above the propellant surface. If a crossflow velocity is not present and a turbulent boundary layer has not been calculated (IEDY=0) then a value of unity is returned.

AFHC. This subroutine calculates the average flame standoff distance parameter, AFH, for each of the diffusion flames. The expressions thus derived are appropriate only for parabolic conical flames.

ETA. This subroutine controls the calculational flow for determining the nondimensional diffusion flame standoff distance, ETA. INDEX

is a control parameter; if INDEX equals 1, the final diffusion flame is calculated and if INDEX equals 2, the primary diffusion flame is calculated.

BURKES. This subroutine performs the Burke-Schumann series solution in order to determine the diffusion flame standoff distances for either the final diffusion flame (INDEX=1) or the primary diffusion flame (INDEX=2). A Newton iteration numerical scheme is employed in order to converge upon a solution. In either the final flame or the primary flame calculations, a test is performed to determine whether the flame closes over the oxidizer surface or over the fuel binder surface. During erosive burning calculations, an iteration on the Burke-Schumann diffusivity related parameter, ZSI, must be performed due to the enhancement of the mass diffusivity coefficient.

DISTF. This subroutine calculates the oxidizer distribution function from known oxidizer particle size distribution data.

LSQFIT. This subroutine takes calculated burning rate versus combustion pressure data and performs a linear least square fit in order to determine the St. Robert's law proportionality constant, C, and the pressure exponent, XN. A goodness of fit correlation coefficient, RSQ, is also returned.

INTEG. This subroutine performs a Simpson's integration over all the oxidizer particle diameters for mode number, M, of the argument array, ARG(541). The primary purpose of this subroutine is in the calculation of the overall burning rate or response function of a propellant based upon the calculated pseudo-propellant burning rates or response functions. INDEX is a control parameter; if INDEX equals 0, the integration is performed over NDPM oxidizer diameters and if INDEX equals 1, the integration is performed over NXDPM oxidizer diameters.

BROOT. This subroutine provides the value of the Jth zero of the Bessel function of the first kind of order one,  $J_1$ .

BESSEL. This subroutine calculates the Bessel functions of the first kind of order zero and one that are used in the Burke-Schumann diffusion flame series solution.

CCAL. This subroutine computes the constant of proportionality, CX, in the expression for the volume of fuel binder associated with an oxidizer particle of a given diameter. A Simpson's integration analysis is performed with the answer being related to the assumed diameter exponent, XN, and the oxidizer distribution function, XFSKP(541).

QUAD. This is a utility subroutine that fits a second order curve through three pairs of variables.

CUBIC. This is a utility subroutine that fits a third order curve through four pairs of variables.

PRESIN. This subroutine is called by LINK00 in order to increment the combustion pressure. Within a burning rate versus combustion pressure calculation, this subroutine calculates NPRESS pressures logarithmically spaced between PSTART and PSTOP.

OXDATA. This subroutine contains data corresponding to the thirty-three propellant formulations supplied by the RPL for investigation. This subroutine is called in INPUT if NPRP, the propellant number, is nonzero. For every propellant formulation, the oxidizer particle size distribution data is supplied, the fuel binder type is designated and all other parameters related to various propellant formulation additives are provided. Adiabatic flame temperature and molecular weight data required by subroutine FLAMET are also provided for each propellant formulation.

### C. OVERLAY (PEM1,1,0)

LINK10. This program routine is the main control routine in OVERLAY (PEM1,1,0). Its primary function is calling subroutine EROSIV.

EROSIV. This subroutine controls the flow of the erosive burning calculations. The principal function of this subroutine is to iterate on an erosive burning rate that is consistent with the enhanced values of the transport properties due to the presence of a turbulent boundary layer above the burning propellant surface. The many control parameters read in through the EROSDT namelist aid in the rapid convergence upon the erosive burning rate for a given propellant formulation subjected to a prescribed crossflow environment. Aside from a control nature, this subroutine stores much of the intermediate results for future output, directs much of the output, and calls HAMRV and DERRV if velocity coupled response is to be calculated.

HAMRV. This subroutine directs the program flow for the nonsteady state velocity coupled response using the small perturbation method. The nonsteady state velocity coupled response is not calculated in this subroutine; this function is performed in the routine LINK20. However, the perturbation of the steady state erosive burning model equations is performed whenever the control parameter, IRVHM, equals one. For each pseudo-propellant, the crossflow velocity and the surface temperature is perturbed systematically within the framework of the steady state erosive burning rate calculations and the various g parameters, referred to in the theoretical analysis portion of the final report of this contract under separate cover, can be calculated and stored for future use in LINK20. From the values of the g parameters thus calculated, four parameter

arrays, C(55,1), C(55,2), C(55,3) and C(55,4), can be generated. Also, the zero frequency limit of the velocity coupled response function, the crossflow velocity exponent array, PXNE(55), can be filled.

DERRV. This subroutine directs the program flow for the nonsteady state velocity coupled response using either the method of Lengelle or the Zeldovich/Novozhilov method. The nonsteady state velocity coupled response is not calculated in this subroutine; this function is performed in the routine LINK20. However, the steady state h parameters, referred to in the theoretical analysis portion of the final report of this contract under separate cover, are calculated via a systematic perturbation of the crossflow velocity and the initial solid propellant temperature. The following steady state combustion parameter arrays thus calculated are as follows. The corresponding h parameter designation is also given where applicable.

- |          |                                                                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PXNE(55) | an array of pseudo-propellant crossflow velocity exponents ( $h_1$ ).                                                                                      |
| PXM(55)  | an array of values related to the pseudo-propellant's sensitivity of surface temperature to changes in the crossflow velocity ( $h_3$ ).                   |
| PXK(55)  | an array of values related to the pseudo-propellant's sensitivity of erosive burning rate to changes in initial solid propellant temperature ( $h_2$ ).    |
| PXS(55)  | an array of pseudo-propellant erosive burning temperature sensitivities.                                                                                   |
| PXR(55)  | an array of values related to the pseudo-propellant's sensitivity of surface temperature to changes in the initial solid propellant temperature ( $h_4$ ). |

- PXD(55)      an array of pseudo-propellant properties ( $h_1h_4-h_2h_3$ ).
- ES1(55)      an array of pseudo-propellant effective surface activation energies via the crossflow velocity perturbation scheme.
- ES2(55)      an array of pseudo-propellant effective surface activation energies via the initial solid propellant temperature perturbation scheme.

EDYCAL. This subroutine calculates the turbulent boundary layer velocity profile and the subsequent average resistivity profile as a function of the surface normal coordinate, Y. A fourth order Runge-Kutta scheme is employed in solving the governing first order differential boundary layer equation in the variable, DUDY. The following variables are used within this analysis:

- REINF      the Reynolds number based on the crossflow velocity, the hydraulic diameter, DIAH, and the boundary layer gas properties of density, RHOBL, and viscosity, XMEWBL.
- CFZERO      the value of the coefficient of friction at the propellant surface without surface blowing.
- CF      the value of the coefficient of friction at the propellant surface with surface blowing.
- AMINJ      the surface mass blowing strength.
- TAUW      the shear stress at the propellant surface with surface blowing.
- TAUWZ      the shear stress at the propellant surface without surface blowing.
- BLOW      the surface blowing parameter.

SURFAV. This subroutine calculates the surface average value of an array so specified. IBIN is a control parameter; if IBIN equals 0, the average is based upon the oxidizer surface and if IBIN equals 1, the average is based upon the fuel binder surface.

SLOPE. This subroutine calculates the derivative of the variable, DUDY, as a function of the surface normal coordinate, YPOS. This is used in the fourth order Runge-Kutta scheme performed in EDYCAL.

YGRID. This subroutine sets up the grid spacing in the surface normal coordinate for the numerical velocity profile calculation performed in EDYCAL.

COEF. This subroutine determines the value of the coefficient of skin friction for channel flow with zero surface blowing. The effect of surface roughness, RUFFAV, is taken into account.

CFCFZ. This subroutine calculates the reduction in skin friction which occurs due to the presence of surface blowing. Any one of four different expressions can be evoked via the IBLOW control parameter.

LIST. This subroutine is a general purpose subroutine which lists the numerical values of a given array, VAR(N).

#### D. OVERLAY (PEM2,2,0)

LINK20. This program routine is the main control routine in OVERLAY (PEM2,2,0). Its primary function is calling subroutine NSINTG.

NSINTG. This subroutine controls the flow of the nonsteady state response calculations. Depending on the control parameters entered via the RESPDT namelist, either the pressure coupled response or the velocity coupled response can be calculated for each pseudo-propellant. Four

pressure coupled response models can be selected; the small perturbation technique (IRPHM=1), the Zeldovich/Novozhilov method (IRPZN=1), the Denison and Baum/Cohen technique (IRPDB=1), and the original Denison and Baum technique (IRPDB=2). Likewise, four velocity coupled response models can be selected; the small perturbation technique (IRVHM=1), the Zeldovich/Novozhilov method (IRVZN=1), the Lengelle technique based on the Denison and Baum/Cohen pressure coupled model (IRVDB=1), and the Lengelle technique based on the original Denison and Baum pressure coupled model (IRVDB=2). After each pseudo-propellant response has been calculated for a given value of frequency, the overall propellant response function can be determined via an integration over all oxidizer particle diameters within the propellant formulation. Either a series summation scheme (IKING=0) or a parallel summation scheme (IKING=1) can be employed. In this manner the overall propellant response function is determined for NOMEQ values of frequency between OSTART and OSTOP. During this procedure, the overall propellant response versus frequency data is read onto a tape for future storage and/or plotting.

RESPON. This subroutine calculates the pseudo-propellant response as required by NSINTG for the data determined in HAMRP and DERRP for the pressure coupled response and HAMRV and DERRV for the velocity coupled response.

QINTER. This is a utility subroutine that performs a quadratic interpolation of an arbitrary variable at a given oxidizer diameter when the value of the variable is known only at discrete oxidizer diameters. This routine is used in the nonsteady state integration schemes.

PHASE. This is a utility subroutine that calculates the phase angle and magnitude of a complex variable, ZETA. The real part of the

complex number, XR, the imaginary part of the complex number, XI, the magnitude, XMAG, and the phase angle in degrees, PHI, are all returned to the calling routine.

ABCAL. This subroutine controls the calculation of the Denison and Baum A and B parameter based upon the Cohen postulates relating the peak pressure coupled response, RPP, and the frequency of the peak, FREQP, to pseudo-propellant properties.

ABCONV. This subroutine performs a secant iteration on the Denison and Baum A parameter for a particular pseudo-propellant. The converged value of A with its corresponding B parameter returned to ABCAL are consistent with the Cohen postulates.

AFIND. This subroutine computes the minimum and maximum values of the Denison and Baum A parameter for a particular pseudo-propellant. These values are used in the iteration scheme in ABCONV.

BCAL. This subroutine calculates a value of the Denison and Baum B parameter for a given A value.

DIFCAL. This subroutine calculates the derivative of the Denison and Baum response with respect to the nondimensional frequency. This information is also used in the secant iteration scheme employed by ABCONV.

#### E. OVERLAY (PEM3,3,0)

LINK30. This program routine is the main control routine in OVERLAY (PEM3,3,0). Its primary function is calling subroutine BPLOT.

BPLOT. This subroutine, a general purpose plotting routine, controls the plotting of the nonsteady state pressure coupled or velocity coupled response versus frequency data generated by the computer program. The

plotting control parameters are entered via formatted read statements within this subroutine. The data to be plotted is read in via binary tape read statements or formatted read statements in subroutine DATPLT. The type of plots generated are box style with the lower x axis being annotated while either of the two y axes being annotated. Both linear and logarithmic axes can be generated. This plotting routine is heavily commented throughout the program listing so therefore, little description will be given here. This plotting routine contains many of the standard CALCOMP calls and should be compatible on most computer systems. However, the user maintains the option to substitute his own plotting routine if so desired.

AXISRG. This subroutine controls the generation of a linear axis. Any one of three axes can be annotated in this fashion; the bottom x axis and either of the two y axes.

LOGAX. This subroutine controls the generation of a logarithmic axis. Any one of three axes can be annotated in this fashion; the bottom x axis and either of the two y axes.

CFIT. This is a general purpose curve fitting routine used in conjunction with the plotting routine. In order to generate smooth response curves from the calculated discrete response function/frequency data points, curve fits are assigned between points with additional data to be plotted being generated. As before, this routine is highly commented within the program listing and little more will be thus added.

OUTP. This subroutine is a general purpose subroutine which lists the response function versus frequency data being plotted. The results of the curve fitting subroutine, CFIT, are also incorporated within this data listing.

DATPLT. This subroutine controls the plotting once the plot format has been generated. The data to be plotted is either read in through formatted read statements or via binary tape reading. If curve fitting of the data is to be carried out, this routine directs the flow of the program to CFIT. IFLAG is a control parameter described in BPLLOT which directs the plotting.

#### IV. INPUT PARAMETERS

##### A. INTRODUCTION

In this section, each input parameter is defined. The input data required for execution of the computer program are entered by both namelist input and formatted read statements. In all cases, the seven namelists, FLAG, PARMST, PROPD, ALUMD, EROSD, RESP, and OXDIST, are entered. In general, only those parameters and data pertinent to the particular problem being considered must be entered. Many input parameters have default values and do not need to be specified unless values other than the default values are to be entered. Where applicable, the default value of the individual input parameters is given in parentheses.

##### B. NAMELIST FLAG

The parameters entered in namelist FLAG control some of the aspects pertaining to the steady state modeling.

IBDP        If IBDP equals 1, each oxidizer particle size distribution is treated as being monodisperse (0).

IKING        If IKING equals 0, burning rate is calculated with a series summation technique. If IKING equals 1, burning rate is calculated with a parallel summation technique. If IKING is

not equal to either 0 or 1, other combination summation techniques are employed (0).

IPRNT1 If IPRNT1 equals 1, the namelist groupings are printed (0).

IPRNT2 If IPRNT2 equals 1, an expanded surface energy iteration output is produced (0).

ISLIP If ISLIP equals 1, a diffusion flame slipline is assumed. The fuel and oxidizer surface mass fluxes are constrained to be equal (1).

ITFAD If ITFAD equals 1, adiabatic flame temperatures and molecular weights are inputted at three pressures for the propellant formulation under consideration (0).

ITS2 If ITS2 equals 1, a two surface temperature analysis is performed (0).

NSOX If NSOX equals 1, the oxidizer surface geometry can be inputted, bypassing the calculations performed in subroutine SOXCAL (0).

### C. NAMELIST PARMST

Parameters pertaining to the numerical analyses within the combustion model are inputted through the namelist PARMST. Also, external environmental conditions such as the pressure and initial solid propellant temperature are specified through this namelist grouping.

ERRBES Minimum magnitude of the last term considered in the Burke-Schumann diffusion flame series solution (.0000001).

ESTART Initial guess for the value of the nondimensional diffusion distance in the Burke-Schumann diffusion flame series solution (.1).

|           |                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ETALIM    | Convergence limit on the nondimensional diffusion distance in the Burke-Schumann diffusion flame series solution (.00001).                                        |
| ITLIM2    | Iteration limit on the nondimensional diffusion distance in the Burke-Schumann diffusion flame series solution (20).                                              |
| ITLIM3    | Surface temperature iteration limit (20).                                                                                                                         |
| LIMBES    | Maximum number of terms taken in the Burke-Schumann diffusion flame series solution (40).                                                                         |
| NARRAY(5) | An array specifying the number of pseudo-propellant diameters per mode, where the index is the total number of modes considered, MODES (21,15,15,13,11).          |
| NXDFAC    | Number of diameter increments between consecutive pseudo-propellant diameters used in nonsteady state response calculations (10).                                 |
| NPRESS    | Number of pressures that are to be considered in a rate versus pressure calculation (1).                                                                          |
| PSTART    | Starting pressure for rate versus pressure calculations or the assigned pressure for the erosive burning or nonsteady state response calculations (68.0272 atm.). |
| PSTOP     | Stopping pressure for rate versus pressure calculations or the assigned pressure for the erosive burning or nonsteady state response calculations (68.0272 atm.). |
| SOXP      | The ratio of the total oxidizer surface area to the planar oxidizer surface area so specified when NSOX = 1 (1.0).                                                |
| TSLIM     | Convergence limit on the surface temperature in the surface temperature iteration scheme (.01 K).                                                                 |
| TSMAX     | Maximum surface temperature allowed in the surface temperature iteration scheme (2500 K).                                                                         |

|        |                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TSMIN  | Minimum surface temperature allowed in the surface temperature iteration scheme (750 K).                                                                                         |
| TSST   | Starting surface temperature in the surface temperature iteration scheme (950 K).                                                                                                |
| TZERO  | Initial solid propellant temperature (294.15 K).                                                                                                                                 |
| XN     | Oxidizer particle diameter exponent utilized in the expression for the volume of fuel associated with an oxidizer particle of a given diameter (3.0).                            |
| XNUHI  | Maximum value for the oxidizer volume fraction for which the Burke-Schumann diffusion flame series solution is rigorously executed (approximation used for larger values) (.98). |
| XNULOW | Minimum value for the oxidizer volume fraction for which the Burke-Schumann diffusion flame series solution is rigorously executed (approximation used for smaller values) (.3). |

#### D. NAMELIST PROPD

Parameters pertaining to the actual propellant under consideration are inputted through this namelist. That is, the various oxidizer, fuel and non-aluminum solid phase and gas phase properties are specified by this namelist grouping.

|           |                                                                                                                                                |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------|
| AAP       | Pre-exponential frequency factor for the oxidizer mono-propellant flame reaction kinetics ( $2.5 \times 10^6 \text{ cm}^3\text{-g/s-atm}^a$ ). |
| AF        | Pre-exponential frequency factor for the fuel binder surface decomposition reaction-HTPB ( $299 \text{ g/cm}^2\text{-s}$ ).                    |
| ALFADD(2) | An array specifying the mass fractions of a possible two non-aluminum and non-catalyst additives (0,0).                                        |

|        |                                                                  |
|--------|------------------------------------------------------------------|
| ALFCAT | Mass fraction of catalyst (0.0).                                 |
| AMW1   | Molecular weights of final combustion products at three values   |
| AMW2   | of pressure: 34.0136, 68.0272, and 136.0544 atmospheres,         |
| AMW3   | respectively. These values are calculated via the NASA           |
|        | Thermochemistry Program based on the propellant formulation      |
|        | considered. Default values are for an 88 percent AP/12           |
|        | percent HTPB propellant (25.881, 25.987, 26.083 g/gmole).        |
| AOX    | Pre-exponential frequency factor for the oxidizer decomposition  |
|        | reaction-AP ( $16600 \text{ g/cm}^2\text{-s}$ ).                 |
| APF    | Pre-exponential frequency factor for the primary flame reaction  |
|        | kinetics ( $1400 \text{ cm}^3\text{-g/s-atm}^b$ ).               |
| APW1   | Molecular weights of the oxidizer decomposition flame combustion |
| APW2   | products at three values of pressure: 34.0136, 68.0272, and      |
| APW3   | 136.0544 atmospheres, respectively. These values are cal-        |
|        | culated via the NASA Thermochemistry Program for AP (27.859,     |
|        | 27.917, 27.982 g/gmole).                                         |
| CAP    | Constant in the exponential expression for the oxidizer mono-    |
|        | propellant flame activation energy in the presence of a          |
|        | catalyst (0.0).                                                  |
| CIGN   | Proportionality factor in the oxidizer ignition delay expression |
|        | ( $190 \text{ s-atm}^m/\text{cm}^n$ ).                           |
| CP     | Specific heat of the gas phase (.4 cal/g-K).                     |
| CPF    | Constant in the exponential expression for the primary flame     |
|        | activation energy in the presence of a catalyst (14.96).         |
| CS     | Specific heat of the solid phase (.2 cal/g-K).                   |
| DELAP  | Oxidizer monopropellant flame reaction order-a (1.0).            |

DELPF Primary flame reaction order-b (1.5).

EAP Activation energy for the oxidizer monopropellant flame reaction kinetics (25000 cal/gmole).

EAP2 Limiting value of the oxidizer monopropellant flame activation energy in the presence of a catalyst (0 cal/gmole).

EF Activation energy for the fuel binder surface decomposition reaction-HTPB (16900 cal/gmole).

EOX Activation energy for the oxidizer decomposition reaction-AP (21000 cal/gmole).

EPF Activation energy for the primary flame reaction kinetics (15000 cal/gmole).

EPF2 Limiting value of the primary flame activation energy in the presence of a catalyst (2610 cal/gmole).

FACTOR Ratio of the change in flame temperature to a change in the initial solid propellant temperature (1.0).

GAMMA Constant of proportionality for the expression which relates the mass diffusion coefficient for the combustion gases to the mass diffusion coefficient at STP ( $.0000076 \text{ cm}^2\text{-atm/K}^{1.75}\text{-s}$ ).

IADD Number of non-aluminum, non-catalyst additives considered (0).

IADTYP(2) Array specifying the additive type: 0 - no additive, 1 - Zirconium carbide (ZrC), 2 - Graphite (0,0).

ICAT Value specifying the catalyst type: 0 - no catalyst, 1 -  $\text{Fe}_2\text{F}_3$ , 2 -  $\text{Fe}_2\text{O}_3$ , 3 - CuPh, 4 - Ferrocene (0).

IFUEL Value specifying the fuel binder type: 1 - HTPB, 2 - PBAN (1).

PLAMB Thermal conductivity of solid phase of propellant ( $.0003 \text{ cal/cm-s-K}$ ).

|       |                                                                                                                                                                                                                                            |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| POWD  | Oxidizer particle diameter exponent in the oxidizer ignition delay expression-n (.80).                                                                                                                                                     |
| POWIG | Pressure exponent in the oxidizer ignition delay expression-m (.721).                                                                                                                                                                      |
| QFUEL | Heat of pyrolysis of fuel binder-HTPB (433 cal/g).                                                                                                                                                                                         |
| QL    | Oxidizer latent heat of decomposition-AP (0.0 cal/g).                                                                                                                                                                                      |
| RHOF  | Density of fuel binder-HTPB (.92 g/cm <sup>3</sup> ).                                                                                                                                                                                      |
| RHOX  | Density of oxidizer-AP (1.95 g/cm <sup>3</sup> ).                                                                                                                                                                                          |
| SPSUR | Specific surface of catalyst (0.0 cm <sup>2</sup> /g).                                                                                                                                                                                     |
| TF1   | Adiabatic flame temperature of final combustion products at                                                                                                                                                                                |
| TF2   | three values of pressure: 34.0136, 68.0272, and 136.0544                                                                                                                                                                                   |
| TF3   | atmospheres, respectively. These values are calculated via the NASA Thermochemistry Program based on the propellant formulation considered. Default values are for an 88 percent AP/12 percent HTPB propellant (2969.4, 3013.7, 3053.6 K). |
| XLAMB | Constant of proportionality for the expression which relates the thermal conductivity for the combustion gases to the thermal conductivity at STP (.00005 cal/cm-s-K <sup>1.5</sup> ).                                                     |
| XNUFF | Final flame stoichiometry variable used in the Burke-Schumann diffusion flame analysis-AP/HTPB (9.3).                                                                                                                                      |
| XNUPF | Primary flame stoichiometry variable used in the Burke-Schumann diffusion flame analysis-AP/HTPB (9.3).                                                                                                                                    |

#### E. NAMELIST ALUMDT

Parameters related to the aluminum particle combustion modeling within the PEM are inputted through this namelist.

BETA        Mass fraction of metal within the propellant formulation (0.0).  
BETAC       Aluminum particle burning rate power law constant ( $.004 \text{ cm}^2/\text{s}$ ).  
CPM        Aluminum solid and liquid phase specific heat ( $.214 \text{ cal/g-K}$ ).  
DBARM       Fifty percent weight mean diameter of aluminum particle size distribution within propellant (6 microns).  
DELC        Aluminum particle diameter exponent in power law burning expression (2.0).  
DELHR       Aluminum heat of combustion ( $1800 \text{ cal/g}$ ).  
G            Gravitational constant ( $980 \text{ cm/s}^2$ ).  
GSUR        Imposed acceleration field (+ into propellant) ( $0.0 \text{ cm/s}^2$ ).  
IALUM       Value specifying aluminum type: 0 - no aluminum, 1 - Al, 2 -  $\text{Al}_2\text{O}_3$  (0).  
IMET        Number of steps in aluminum combustion integration (30).  
IALST        Number of steps in aluminum surface emergence integration (100).  
IPRNT4      If IPRNT4 equals 1, an expanded aluminum interaction output is produced (0).  
ISINK        Value specifying aluminum model to employ: 0 - full aluminum emergence/ignition/combustion model, 1 - simplified heat sink model (0).  
QM          Latent heat of liquifaction of aluminum ( $96 \text{ cal/g}$ ).  
RHOL        Density of liquid aluminum ( $2.35 \text{ g/cm}^3$ ).  
RHOM        Density of solid aluminum ( $2.71 \text{ g/cm}^3$ ).  
SIGMAM      Mode width parameter of aluminum particle size distribution (1.0).

TMELT      Melting point temperature of solid aluminum (933 K).  
TSMELT     Melting point temperature of  $\text{Al}_2\text{O}_3$  (2320 K).

#### F. NAMELIST EROSDT

Parameters related to the erosive burning modeling within the PEM are inputted through this namelist.

CONC      Proportionality constant in the relation between the molecular and turbulent thermal conductivities and the molecular and turbulent viscosities (1.0).  
COND      Proportionality constant in the relation between the molecular and turbulent mass diffusion coefficients and the molecular and turbulent viscosities (1.0).  
CPRIME    Proportionality constant in the Prandtl mixing length equation used in the turbulent boundary layer analysis (.16).  
DIAH      The hydraulic diameter of the flow channel above the burning propellant surface (2.0 cm).  
DYIN      Initial increment in the surface normal direction in the numerical velocity profile calculational grid (.000001 cm).  
EBRLIM    Convergence limit on the erosive burning rate (.0001 cm/s).  
ERATE(10) Array of erosive burning rates or surface blowing rates used to expedite erosive burning convergence (10\*1.0 cm/s).  
IBLOW     Parameter designating the appropriate expression for the reduction in the skin friction coefficient under the influence of surface blowing (4).  
IEFLAG    Erosive burning control parameter: If IEFLAG is negative, investigate ABS(IEFLAG) rates from the array ERATE (10) with velocity profiles listed for each rate; if IEFLAG is equal to zero, perform normal iteration on the erosive

burning rate; if IEFLAG is positive, investigate IEFLAG rates from the array ERATE(10) without velocity profiles being listed (0).

- IEPRT1     Erosive burning control parameter: If IEPRT1 equals 0, no velocity profiles are listed; if IEPRT1 equals 1, only the final iterations velocity profile is listed; if IEPRT1 equals 2, velocity profiles for all iterations are listed.
- IEPRT2     If IEPRT2 is equal to 1, an expanded erosive burning output is provided (0).
- IERATE     If IERATE is equal to 1, the normal erosive burning iteration is performed with the first rate being equal to ERATE(1) (0).
- INSTEP     Number of increments in the surface normal direction per logarithmic cycle in the numerical velocity profile calculational grid (100).
- IPRNT3     If IPRNT3 equals 1, print the velocity profile numerical scheme (0).
- IROUGH     If IROUGH equals 1, surface roughness is taken into account in the calculation of the skin friction coefficient (1).
- ITERO     Maximum number of iterations allowed in the erosive burning rate numerical solution (20).
- ITLIM1     Iteration limit on the nondimensional diffusion coefficient of the Burke-Schumann diffusion flame series solution under the influence of erosive burning (10).
- NCYC     Number of logarithmic cycles in the surface normal direction used in the numerical erosive burning calculational grid (5).

|        |                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UINF   | Value of the free stream crossflow velocity used in the erosive burning calculations (0.0 cm/s).                                                                                 |
| XMEW   | Constant of proportionality for the expression which relates the molecular viscosity for the combustion gases to the molecular viscosity at STP ( $.00002 \text{ g/cm-s-K}^5$ ). |
| YSTART | Starting value of the surface normal coordinate used in the numerical erosive burning calculational grid (0.0 cm).                                                               |
| ZSILIM | Convergence limit on the nondimensional diffusion coefficient of the Burke-Schumann diffusion flame series solution under the influence of erosive burning (.00001).             |

#### G. NAMELIST RESPDT

Parameters related to the nonsteady state response modeling within the PEM are inputted through this namelist.

|       |                                                                                                                                                                                                                                      |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BFAC  | Proportionality constant for the Cohen postulate for the magnitude of the Denison and Baum pressure coupled response at the peak frequency (1360 microns).                                                                           |
| FFAC  | Proportionality constant for the Cohen postulate of the peak frequency of the Denison and Baum pressure coupled response (4.72).                                                                                                     |
| IPHMG | If IPHMG equals 1, phase and magnitude information is listed for the pressure and velocity coupled response functions (1).                                                                                                           |
| IRPDB | If IRPDB equals 1, calculate the pressure coupled response function with the Denison and Baum/Cohen technique. If IRPDB equals 2, calculate the pressure coupled response function with the original Denison and Baum technique (0). |

IRPHM      If IRPHM equals 1, calculate the pressure coupled response function with the small perturbation technique (0).

IRPZN      If IRPZN equals 1, calculate the pressure coupled response function with the Zeldovich/Novozhilov technique (0).

IRVDB      If IRVDB equals 1, calculate the velocity coupled response function based on the analysis of Lengelle with the pressure coupled response calculated with the Denison and Baum/Cohen technique. If IRVDB equals 2, calculate the velocity coupled response function in the same manner, however, the pressure coupled response is calculated with the original Denison and Baum technique (0).

IRVHM      If IRVHM equals 1, calculate the velocity coupled response function with the small perturbation technique applied to the erosive burning model (0).

IRVZN      If IRVZN equals 1, calculate the velocity coupled response function with the Zeldovich/Novozhilov technique applied to the erosive burning model (0).

NOMEG      Number of frequencies for which the nonsteady state response functions are calculated (81).

NPLOT      Number of tape containing response function versus frequency data to be plotted. If NPLOT equals 0, no plotting is performed (0).

NSFLAG      If NSFLAG equals 1, expanded nonsteady state analysis output is generated (0).

OSTART      First frequency for which the nonsteady state response function is calculated (10 cycles/s).

OSTOP      Last frequency for which the nonsteady state response function is calculated (100000 cycles/s).

|       |                                                                                                                                 |
|-------|---------------------------------------------------------------------------------------------------------------------------------|
| PPER  | Pressure perturbation parameter used in the pressure coupled small perturbation technique (.005).                               |
| PPERD | Pressure perturbation parameter used in the pressure coupled Zeldovich/Novozhilov technique (.005).                             |
| TPERD | Initial solid propellant temperature perturbation parameter used in the pressure coupled Zeldovich/Novozhilov technique (.005). |
| TSPER | Surface temperature perturbation parameter used in the pressure and velocity coupled small perturbation techniques (.005).      |
| UPER  | Crossflow velocity perturbation parameter used in the velocity coupled small perturbation technique (.005).                     |
| UPERD | Crossflow velocity perturbation parameter used in the velocity coupled Zeldovich/Novozhilov technique (.005).                   |

#### H. NAMELIST OXDIST

Parameters describing the oxidizer particle size distribution of the propellant are inputted through this namelist.

|          |                                                                                                                                                                                                                                |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ALFAI(5) | Array representing the mass fraction for each of the oxidizer modes (.88,0.0,0.0,0.0,0.0).                                                                                                                                     |
| DBARI(5) | Array representing the fifty percent weight mean diameter for each of the oxidizer modes (80.,0.0,0.0,0.0,0.0,0.0 microns).                                                                                                    |
| MODES    | Parameter specifying the number of oxidizer modes (1).                                                                                                                                                                         |
| NEXTC    | Control parameter. If NEXTC equals 0, the program will stop after executing case depicted by the previous namelists. If NEXTC equals 1, seven new namelists are called after execution in order to run an additional case (0). |

NPROP        Parameter representing a particular propellant number  
              for which oxidizer particle size distribution data as  
              well as fuel and additive information are available  
              with a call to subroutine OXDATA (0).

SIGMAI(5)    Array representing the mode width parameter for each of  
              the oxidizer modes (2.0,0.0,0.0,0.0,0.0).

#### I. PLOTTING ROUTINE INPUT

The input to the plotting routine is the only formatted read input used in the PEM computer program. Below is a list of the various read statements, the format required, and a brief description of the parameters involved. As stated previously, since the plotting routine is highly commented throughout its listing, only brief descriptions of the many parameters are given in this section. The user is referred to the program listing of the plotting routine available upon request from AFRPL for further information.

CARD 1    READ; XSIZE, YSIZE, NANNOT, NFLUSH

            FORMAT (2F10.0,2I5)

XSIZE        size of the x axis in millimeters.  
YSIZE        size of the y axis in millimeters.  
NANNOT       y axis annotation control parameter.  
NFLUSH       axis labeling centering control parameter.

CARD 2    READ; XMIN, XMAX, NXDIV, NXTYPE, NFX, XFORM

            FORMAT (2F10.0,3I5,A10)

XMIN        minimum x axis value.  
XMAX        maximum x axis value.  
NXDIV       number of x axis divisions.  
NXTYPE       x axis type control parameter.

NFX            x axis numbering format length.  
XFORM        x axis numbering format.

CARD 3 READ; XHGHTN, XHGHT, NXS, XSTRNG

FORMAT (2F5.0,I10,6A10)

XHGHTN       x axis number height in millimeters  
XHGHT        x axis labeling height in millimeters  
NXS           number of characters in axis annotation.  
XSTRNG       x axis annotation.

CARD 4 READ; YMIN, YMAX, NYDIV, NYTYPE, NFY, YFORM

FORMAT (2F10.0,3I5,A10)

YMIN          minimum left y axis value.  
YMAX          maximum left y axis value.  
NYDIV        number of left y axis divisions.  
NYTYPE       left y axis type control parameter.  
NFY           left y axis numbering format length.  
YFORM        left y axis numbering format.

CARD 5 READ; YHGHTN, YHGHT, NYS, YSTRNG

FORMAT (2F5.0,I10,6A10)

YHGHTN       left y axis number height in millimeters.  
YHGHT        left y axis labeling height in millimeters.  
NYS           number of characters in left y axis annotation.  
YSTRNG       left y axis annotation.

CARD 6 READ; YMINR, YMAXR, NYDIVR, NYTYPR, NFYR, YFORMR

FORMAT (2F10.0,3I5,A10)

YMINR        minimum right y axis value.  
YMAXR        maximum right y axis value.  
NYDIVR       number of right y axis divisions.

NYTYPR      right y axis numbering format length.

YFORMR      right y axis numbering format.

CARD 7    READ; YHGTNR,YHGHTR, NYSR, YSTNGR

          FORMAT (2F5.0,I10,6A10)

YHGTNR      right y axis number height in millimeters.

YHGHTR      right y axis labeling height in millimeters.

NYSR         number of characters in right y axis annotation.

YSTNGR      right y axis annotation.

CARD 8    READ; XORIG, YORIG

          FORMAT (2F10.0)

XORIG        reference x origin in millimeters.

YORIG        reference y origin in millimeters.

CARD 9    READ; NLABEL

          FORMAT (I2)

NLABEL      number of label strings to be plotted.

CARD 10    READ; XPOS, YPOS, HLBL, ANGLE, NCHAR, LABEL

          FORMAT (4F4.0,I4,6A10)

XPOS         starting x value for label string.

YPOS         starting y value for label string.

HLBL         label character height in millimeters.

ANGLE        label angle in degrees.

NCHAR        number of characters in label string.

LABEL        label string.

(note ... there should be NLABEL of the above card)

CARD 11    READ; IFLAG

          FORMAT (I5)

IFLAG        plotting control parameter.

CARD 12 READ; NY, NJ, NONCEN, ICURVF, NPLT, NDIV, ITAPE

FORMAT (7I5)

NY            right or left y axis control parameter.  
NJ            pen control parameter.  
NONCEN       on-center symbol control parameter.  
ICURVF       curve fitting routine control parameter.  
NPLT          number of data points to plot.  
NDIV          number of points to generate in curve fitting  
              routine between consecutive data points.  
ITAPE        number of tape off which to read data to be plotted.

CARD 13 READ; XPLOT(I), YPLOT(I)

FORMAT (2F10.0)

XPLOT        x value of x-y data point.  
YPLOT        y value of x-y data point.

(note ... there should be NPLT of the above card)

## V. OUTPUT INTERPRETATION

The first page of output generated by the computer program consists of a listing of the various input parameters read in through the namelist input groupings. This includes the oxidizer size distribution information, along with the many oxidizer, fuel binder, aluminum and non-aluminum additives properties. Also, the first page of output contains some of the preliminary results of calculations, such as the values of the overall propellant volume fraction of oxidizer and density, and many of the control parameters associated with burning rate versus pressure calculations and nonsteady state calculations. These parameters are listed with their actual variable designation, a brief word description and the numerical values associated with the parameters. Whenever either aluminum modeling or erosive burning modeling is employed, additional calculation input information such as that depicted on the first page of output is provided. The following pseudo-propellant variables calculated within the computer program are also presented:

|       |                                                                 |
|-------|-----------------------------------------------------------------|
| DZERO | the pseudo-propellant oxidizer particle diameter.               |
| BETAF | the fraction of reactants entering into the<br>primary flame.   |
| XSTPD | the primary flame diffusion flame standoff distance.            |
| XSTPF | the primary flame kinetic standoff distance.                    |
| XSTAP | the oxidizer monopropellant flame kinetic standoff<br>distance. |
| XSTFD | the final flame diffusion flame standoff distance.              |
| TF    | the final flame adiabatic flame temperature.                    |

|        |                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------|
| TSPF   | the percent contribution of the primary flame to the overall energy flux at the propellant surface.                 |
| TSFF   | the percent contribution of the final flame to the overall energy flux at the propellant surface.                   |
| TSAP   | the percent contribution of the oxidizer monopropellant flame to the overall energy flux at the propellant surface. |
| TSQL   | surface temperature rise due to oxidizer decomposition.                                                             |
| TSQF   | surface temperature rise due to fuel binder pyrolysis.                                                              |
| TSQM   | surface temperature rise due to metal liquifaction.                                                                 |
| SOXP   | ratio of total oxidizer surface area to planar oxidizer surface area.                                               |
| TSB    | the fuel binder surface temperature (ITS2=1).                                                                       |
| RATE   | the pseudo-propellant linear burning rate.                                                                          |
| XNUV   | the pseudo-propellant oxidizer volume fraction.                                                                     |
| ALFAV  | the pseudo-propellant oxidizer mass fraction.                                                                       |
| RHOV   | the pseudo-propellant density.                                                                                      |
| FSKP   | the pseudo-propellant oxidizer distribution function.                                                               |
| XLAMAP | the oxidizer monopropellant flame zone thermal conductivity.                                                        |
| XLAMPF | the primary flame zone thermal conductivity.                                                                        |
| XLAMFF | the final flame zone thermal conductivity.                                                                          |
| C      | constant of proportionality in St. Robert's burning law.                                                            |
| N      | pressure exponent in St. Robert's burning law.                                                                      |

The following parameters are associated with the aluminum particle combustion modeling within the PEM.

|       |                                                                                                           |
|-------|-----------------------------------------------------------------------------------------------------------|
| VG    | hot gas stream velocity, normal to propellant surface.                                                    |
| DAGGL | liquid metal droplet diameter.                                                                            |
| TIGN  | ignition time referenced from moment of completed emergence.                                              |
| XIGN  | distance above surface at ignition relative to center of aluminum particle.                               |
| DLOFF | diameter of aluminum particle at lift off from surface.                                                   |
| VELP  | velocity of aluminum particle at moment of ignition.                                                      |
| TCOMB | time required for complete combustion after ignition.                                                     |
| XCOMB | distance above surface at moment of complete combustion.                                                  |
| TSAL  | the percent contribution of the aluminum combustion to the overall energy flux at the propellant surface. |

The following parameters are associated with the erosive burning combustion modeling within the PEM.

|         |                                                          |
|---------|----------------------------------------------------------|
| ROUGH   | the average roughness height based on oxidizer geometry. |
| GAMAPF  | the primary flame zone mass diffusivity coefficient.     |
| GMAFF   | the final flame zone mass diffusivity coefficient.       |
| R-EROS  | the pseudo-propellant erosive burning rate.              |
| R-NEROS | the pseudo-propellant nonerosive burning rate.           |
| EBETA   | the pseudo-propellant erosive burning strength.          |
| TSBN    | the fuel binder sensible heat.                           |
| TAVBL   | boundary layer average gas temperature.                  |

|       |                                              |
|-------|----------------------------------------------|
| XMEW  | boundary layer average gas viscosity.        |
| AMWBL | boundary layer average gas molecular weight. |

The following parameters are associated with the nonsteady state response modeling within the PEM.

|            |                                                                                                                                       |
|------------|---------------------------------------------------------------------------------------------------------------------------------------|
| GRAD       | surface heat flux.                                                                                                                    |
| C(JJ,N)    | C parameter for JJth pseudo-propellant (N = 1,4)<br>used in small perturbation response calculations.                                 |
| PXN        | the pseudo-propellant pressure exponent.                                                                                              |
| NDF        | nondimensional frequency.                                                                                                             |
| OMEGA      | frequency in cycles per second.                                                                                                       |
| RE(RSP/N)  | real part of complex normalized response function.                                                                                    |
| IM(RSP/N)  | imaginary part of complex normalized response<br>function.                                                                            |
| RE(RSP)    | real part of complex response function.                                                                                               |
| IM(RSP)    | imaginary part of complex response function.                                                                                          |

| MAG(RSP/N) | magnitude of the complex normalized response function.                                                                                |
| PXK        | value related to the pseudo-propellant's sensitivity<br>of burning rate to changes in initial solid propellant<br>temperature.        |
| PXR        | value related to the pseudo-propellant's sensitivity<br>of surface temperature to changes in initial solid<br>propellant temperature. |

|      |                                                                                                                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PXM  | value related to the pseudo-propellant's sensitivity of surface temperature to changes in combustion pressure (for pressure coupled response) or crossflow velocity (for velocity coupled response).            |
| PXD  | value equal to $d_1d_4 - d_2d_3$ for pressure coupled response calculations and equal to $h_1h_4 - h_2h_3$ for velocity coupled response calculations.                                                          |
| PXS  | the pseudo-propellant temperature sensitivity.                                                                                                                                                                  |
| ES1  | the pseudo-propellant effective surface activation energy calculated via a pressure perturbation for the pressure coupled response and via a crossflow velocity perturbation for the velocity coupled response. |
| ES2  | the pseudo-propellant effective surface activation energy calculated via a initial solid propellant temperature perturbation.                                                                                   |
| A    | the Denison and Baum A parameter.                                                                                                                                                                               |
| B    | the Denison and Baum B parameter.                                                                                                                                                                               |
| AVV  | the Denison and Baum A parameter calculated via a perturbation in the initial solid propellant temperature.                                                                                                     |
| PXNE | the pseudo-propellant crossflow velocity exponent.                                                                                                                                                              |

## VI. SAMPLE CASES

### A. INTRODUCTION

Eleven sample cases are presented in this section to illustrate the applications of the PEM computer program to calculations of both the steady state and the nonsteady state propellant response. For each sample case, a brief discussion of the calculation to be performed is provided. This is followed by a figure depicting the required input data for each case. Finally, the generated computer output is given. In each case, the seven namelist input groupings provide all of the necessary input information. The last sample case, requires formatted data entry in order to generate a plot of the calculated response function versus frequency data. Below is a brief description of these eleven sample cases. Please note that if output is repeated between cases, such output will only be presented once with new output presented for each of the sample cases.

### B. SAMPLE CASE NUMBER 1

This case is a typical burning rate versus combustion pressure calculation for a nonaluminized, unimodal propellant. The oxidizer has a mean diameter of 40 microns while the mode width parameter equals two. The total percent of oxidizer is 88 percent with the fuel binder being HTPB. Three pressures are investigated; 34.0136, 68.0272, and 136.0544 atmospheres. After calculations are completed, the pressure exponent is calculated based upon the obtained results.

IN ST ROBERTS BURNING RATE LAW--  $R = C \cdot P^{**N}$

C = .44887E-01 IN\*\*((1+2N)/SEC-LB\*\*N  
N = .35824E+00

COEFFICIENT OF DETERMINATION = .99938E+00

### C. SAMPLE CASE NUMBER 2

This case represents an aluminum combustion calculation. Again, the oxidizer distribution is unimodal with a mean oxidizer diameter of 40 microns and a mode width parameter equal to two. The mass fractions of oxidizer and aluminum are .68 and .20, respectively. The aluminum particles have a diameter of 24 microns. In this particular case, the adiabatic flame temperatures and molecular weights of the combustion products must be inputted since such information is unavailable in FLAMET. As discussed previously, the NASA Thermochemistry Program has been employed to calculate these values for the propellant formulation considered at the three combustion pressures required. The flame temperatures have been calculated for an initial temperature of 298.15 K while the default initial temperature is 294.15 K. Therefore, a temperature correction will be made to this data.

#### D. SAMPLE CASE NUMBER 3

This case represents an erosive burning rate calculation.

The propellant oxidizer distribution is unimodal with a mean diameter of 40 microns and a mode width parameter equal to two. The oxidizer mass fraction is equal to .88 and the value of the crossflow velocity is 20000 centimeter per second. All other default values are assumed. The output corresponding to this sample case illustrates the convergence routine employed in order to determine the proper value of the erosive burning rate for the given propellant formulation. Five iterations were involved until the burning rate used to calculate the transport property enhancement due to turbulence matched the resulting burning rate. Part of the output consists of the final velocity and resistivity profiles of the turbulent boundary layer.

#### E. SAMPLE CASE 4

This case is the first of the nonsteady state pressure coupled response calculations. The method employed in this case is the small perturbation technique. Again, the propellant oxidizer distribution is unimodal with a mean diameter of 40 microns and a mode width parameter equal to two. The oxidizer mass fraction is equal to .88 and all other default values are assumed. After presenting the nonsteady state response parameters for each of the individual pseudo-propellants, the overall propellant response is presented as a function of the frequency. As is the case with all the nonsteady state response output, the real and imaginary parts of the complex response function is given along with normalized response values, the magnitudes of the response function and the phase angles associated with each frequency.

#### F. SAMPLE CASE 5

This case is a pressure coupled response calculation using the Zeldovich/Novozhilov method. Again, the propellant oxidizer distribution is unimodal with a mean diameter of 40 microns and a mode width parameter equal to two. The oxidizer mass fraction is equal to .88 and all other default values are assumed.

G. SAMPLE CASE 6a

This is the first of two calculations of the pressure coupled response function using the Denison and Baum technique. This case calculates the Denison and Baum A and B parameters for each of the individual pseudo-propellants based upon the Cohen postulates. Again, the oxidizer distribution is unimodal with a mean diameter of 40 microns and a mode width parameter equal to two. The oxidizer mass fraction is equal to .88 and all other default values are assumed.

#### H. SAMPLE CASE 6b

This is the second of two calculations of the pressure coupled response function using the Denison and Baum technique. This case determines the Denison and Baum A and B parameters for each of the individual pseudo-propellants in the manner originally proposed, that is, not subjected to the Cohen postulates. Again, the oxidizer distribution is unimodal with a mean diameter of 40 microns and a mode width parameter equal to two. The oxidizer mass fraction is equal to .88 and all other default values are assumed.

## I. SAMPLE CASE 7

This case is the first of the nonsteady state velocity coupled response calculations. The method employed in this case is the small perturbation technique. However, in this case and in the next two cases, the oxidizer distribution is unimodal with a mean diameter of 40 microns and a mode width parameter equal to one. That is, only one size oxidizer particles are assumed. The reason for the monodisperse consideration is due to the tremendous computational time required by the erosive burning technique. The oxidizer mass fraction is again assumed to be equal to .88 and the other default parameters values are assumed. Since the velocity coupled response model is based upon a perturbation of the erosive burning model equations, a value of crossflow velocity must be specified. In this and the next two cases, the crossflow velocity is assumed to be 20000 centimeters per sec. As was the case for the pressure coupled response function output, the same velocity coupled response function versus frequency results are presented for these three cases.

#### J. SAMPLE CASE 8

This case is a velocity coupled response calculation using the Zeldovich/Novozhilov method. As before, the propellant oxidizer distribution is unimodal with a mean diameter of 40 microns and a mode width parameter equal to one. The oxidizer mass fraction is equal to .88 and all other default values are assumed. The cross-flow velocity is taken to be 20000 centimeters per second. In the output corresponding to this case, the erosive burning calculation is the same as that presented in the previous example. However, additional output representing the perturbation of the crossflow velocity and the initial solid propellant temperature within the erosive burning framework is also presented.

#### K. SAMPLE CASE 9

This case is the final velocity coupled response calculations. This is based on the Lengelle method incorporating the Denison and Baum pressure coupled response function. Therefore, the first portion of the output represents the pressure coupled response for this propellant formulation. This is then followed by the velocity coupled information. Again, the propellant oxidizer distribution is unimodal with a mean diameter of 40 microns and a mode width parameter equal to one. The oxidizer mass fraction is equal to .88 and all other default values are assumed. The crossflow velocity is taken to be 20000 centimeters per second. Again, output corresponding to the perturbation in the crossflow velocity is presented.

#### L. SAMPLE CASE 10

This is the final case to be presented. Unlike the other ten cases, this case is the calculation of the pressure coupled response versus frequency for one of the propellants provided by the RPL. The number designation of the propellant considered is 3-1 (17). The oxidizer distribution does not need to be inputted since this information has been previously encoded within the program via subroutine OXDATA. Therefore, one only need to enter NPROP=17 in the OXDIST namelist. The Zeldovich/Novozhilov pressure coupled response method is being employed and response will be calculated at a pressure of 43.5374 atmospheres and an initial solid propellant temperature of 300 K. Unlike the other nonsteady state response calculations, 121 frequencies are being considered with the data written on TAPE7 being plotted along with available experimental data. The formatted input data given for this case represents what is required to plot the results of the nonsteady state calculations. In this case, both of the y axes are being annotated; the right y axis being the value of the normalized pressure coupled response and the left y axis being a factor of .402 less--thus representing the corresponding non-normalized pressure coupled response. The resulting plot is depicted by Figure 13.
